Process Synchronization(2)

Prof. Hui Jiang

Dept of Computer Science and Engineering

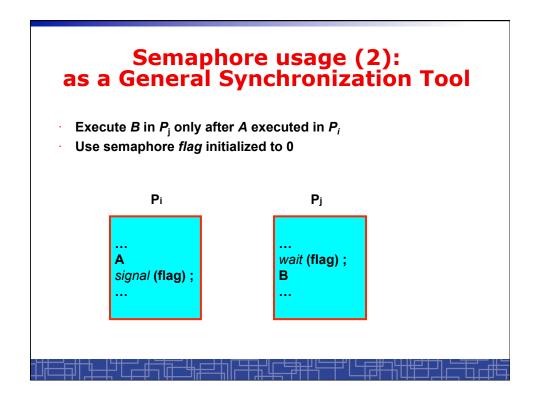

York University

Semaphores

- Problems with the software solutions.
 - Complicated programming, not flexible to use.
 - Not easy to generalize to more complex synchronization problems.
- Semaphore (a.k.a. lock): an easy-to-use synchronization tool
 - An integer variable S

```
- wait(S) {
    while (S<=0);
    S--;
}
- signal(S) {
    S++;
}</pre>
```

Semaphore usage (1): the n-process critical-section problem The n processes share a semaphore, Semaphore mutex; // mutex is initialized to 1. Process Pi do { wait(mutex); critical section of Pi signal(mutex); remainder section of Pi } while (1);

Spinlock vs. Sleeping Lock

- Previous definition of semaphore requires busy waiting.
 - It is called spinlock.
 - spinlock does not need context switch, but waste CPU cycles in a continuous loop.
 - spinlock is OK only for lock waiting is very short.
- Semaphore without busy-waiting, called sleeping lock:
 - In defining wait(), rather than busy-waiting, the process makes system calls to block itself and switch back to waiting state, and put the process to a waiting queue associated with the semaphore. The control is transferred to CPU scheduler.
 - In defining signal(), the process makes system calls to pick a process in the waiting queue of the semaphore, wake it up by moving it to the ready queue to wait for CPU scheduling.
 - Sleeping Lock is good only for long waiting.

Spinlock Implementation(1)

In uni-processor machine, disabling interrupt before modifying semaphore.

```
wait(S) {
    do {
        if(S>0) {
            S--;
            return;
        }
        while(1);
}
```

```
signal(S) {
S++;
return;
}
```

Spinlock Implementation(1)

In uni-processor machine, disabling interrupt before modifying semaphore.

```
wait(S) {

do {
    Disable_Interrupt;
    if(S>0) {
        S--;
        Enable_Interrupt;
        return;
    }
    Enable_Interrupt;
    while(1);
}
```

```
signal(S) {

Disable_Interrupt;
S++;
Enable_Interrupt;
return;
}
```

Spinlock Implementation(2)

- In multi-processor machine, inhibiting interrupt of all processors is not easy and efficient.
- Use software solution to critical-section problems
 - e.g., bakery algorithm.
 - Treat wait() and signal() as critical sections.
- Or use hardware support if available:
 - TestAndSet() or Swap()
- Example: implement spinlock among two processes.
 - Use Peterson's algorithm for protection.
 - Shared data:

Semaphore S; Initially S=1

boolean flag[2]; initially flag [0] = flag [1] = false. int turn; initially turn = 0 or 1.

Spinlock Implementation(3)

```
wait(S) {
    int i=process_ID(); IIO→PO, 1→P1
    int j=(i+1)%2;

do {
    flag [ i ]:= true; I/request to enter
    turn = j;
    while (flag [ j ] and turn = j);
    if (S > 0) { I/critical section
        S--;
        flag [ i ] = false;
        return;
    } else {
        flag [ i ] = false;
    }
} while (1);
}
```

```
signal(S) {
  int i=process_ID(); II0→P0, 1→P1
  int j=(i+1)%2;

flag [i]:= true; IIrequest to enter
  turn = j;
  while (flag [j] and turn = j);

S++; IIcritical section

flag [i] = false;

return;
}
```

Spinlock Implementation(2)

- In multi-processor machine, inhibiting interrupt of all processors is not easy and efficient.
- Use software solution to critical-section problems
 - e.g., bakery algorithm.
 - Treat wait() and signal() as critical sections.
- Or use hardware support if available:
 - TestAndSet() or Swap()
- Example: implement spinlock between N processes.
 - Use Bakery algorithm for protection.
 - Shared data:

```
Semaphore S; Initially S=1
```

 $boolean \ choosing [N]; \ \ (\textbf{Initially} \ false)$

int number[N]; (Initially 0)

Spinlock Implementation(3)

```
wait(S) {
   int i=process_ID();
    choosing[i] = true;
    number[ i ] = max(number[0], number[1],
    ..., number [N – 1])+1;
    choosing[i] = false;
    for (j = 0; j < N; j++) {
      while (choosing[j]);
      while ((number[j]!= 0) &&
             (number[ j ],j)< (number[ i ],i));
  if (S >0) { //critical section
     S--;
    number[i] = 0;
    return;
  number[i] = 0;
 } while (1);
```

Sleeping Lock (I)

Define a sleeping lock as a structure:

```
typedef struct {
  int value; // Initialized to 1
  struct process *L;
} semaphore;
```

- Assume two system calls:
 - block() suspends the process that invokes it.
 - wakeup(P) resumes the execution of a blocked process P.
- Equally applicable to multiple threads in one process.

Sleeping Lock (II)

Semaphore operations now defined as:

Two Types of Semaphores: Binary vs. Counting

- Binary semaphore (a.k.a. mutex lock) integer value can range only between 0 and 1; simpler to implement by hardware.
- Counting semaphore integer value can range over an unrestricted domain.
- We can implement a counting semaphore S by using two binary semaphore.
- Binary semaphore is normally used as mutex lock.
- Counting semaphore can be used as shared counter, load controller, etc...

Implementing counting semaphore with two Binary Semaphores

Data structures:

```
binary-semaphore S1, S2; int C:
```

Initialization:

```
S1 = 1
S2 = 0
C = initial value of semaphore S
```

Implementing S

```
wait(S) operation:
```

signal(S) operation:

```
wait_binary(S1);
C ++;
if (C <= 0)
     signal_binary(S2);
else
     signal_binary(S1);</pre>
```

Classical Synchronization Problems

- The Bounded-Buffer P-C Problem
- The Readers-Writers Problem
- The Dining-Philosophers Problem

Bounded-Buffer P-C Problem

- A producer produces some data for a consumer to consume. They share a bounded-buffer for data transferring.
- Shared memory:
 - A buffer to hold at most *n* items
- Shared data (three semaphores)

```
Semaphore filled, empty; /*counting*/
Semaphore mutex; /* binary */
```

Initially:

filled = 0, empty = n, mutex = 1

Bounded-Buffer Problem: Producer Process

```
do {
...
produce an item in nextp
...
wait(empty);
wait(mutex);
...
add nextp to buffer
...
signal(mutex);
signal(filled);
} while (1);
```

Bounded-Buffer Problem: Consumer Process

```
do {
    wait(filled)
    wait(mutex);
    ...
    remove an item from buffer to nextc
    ...
    signal(mutex);
    signal(empty);
    ...
    consume the item in nextc
    ...
} while (1);
```

The Readers-Writers Problem

- Many processes concurrently access a data object
 - Readers: only read the data.
 - Writers: update and may write the data object.
- Only writer needs exclusive access of the data.
- The first readers-writers problem:
 - Unless a writer has already obtained permission to use the shared data, readers are always allowed to access data.
 - May starve a writer.
- The second readers-writer problem:
 - Once a writer is ready, the writer performs its write as soon as possible.
 - May starve a reader.

The 1st Readers-Writers Problem

- Use semaphore to implement 1st readers-writer problem
- · Shared data:

```
int readcount = 0; // keep track the number of readers
// accessing the data object
```

Semaphore mutex = 1; // mutually exclusive access to // readcount among readers

Semaphore wrt = 1; // mutual exclusion to the data object // used by every writer // also set by the 1st reader to read the data // and clear by the last reader to finish reading

The 1st Readers-Writers Problem

Writer Process

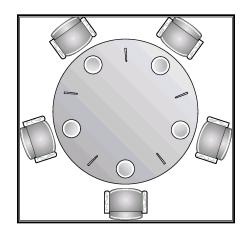

... wait(wrt); ... writing is performed ... signal(wrt);

Reader Process

```
...
wait(mutex);
readcount++;
if (readcount == 1) wait(wrt);
signal(mutex);
...
reading is performed
...
wait(mutex);
readcount--;
if (readcount == 0) signal(wrt);
signal(mutex);
...
```

The Dining-Philosophers Problem

- Five philosophers are thinking or eating
- Using only five chopsticks
- When thinking, no need for chopsticks.
- When eating, need two closest chopsticks.
- Can pick up only one chopsticks
- Can not get the one already in the hand of a neighbor.

The Dining-Philosophers Problem: Semaphore Solution Represent each chopstick with a semaphore Semaphore chopstick[5]; // Initialized to 1

Philosopher i (i=0,1,2,3,4)

```
do {
   wait(chopstick[i]);
   wait(chopstick[(i+1) % 5]);
   ...
   eat
   ...
   signal(chopstick[i]);
   signal(chopstick[(i+1) % 5]);
   ...
   think
   ...
} while (1);
```

Incorrect Semaphore Usage Mistake 1: Mistake 2: Mistake 3: Mistake 4: signal(mutex); wait(mutex) ; wait(mutex) ; Critical **Section** Critical Critical Critical **Section Section Section** signal(mutex); wait(mutex) ; wait(mutex);

Starvation and Deadlock

- Starvation infinite blocking. A process may never be removed from the semaphore queue in which it is suspended.
- Deadlock two or more processes are waiting infinitely for an event that can be caused by only one of the waiting processes.
- Let S and Q be two semaphores initialized to 1

```
\begin{array}{cccc} P_0 & P_1 \\ wait(S); & wait(Q); \\ wait(Q); & wait(S); \\ \vdots & \vdots \\ signal(S); & signal(Q); \\ signal(Q) & signal(S); \end{array}
```

double_rq_lock() in Linux Kernel

```
double_rq_lock(struct runqueue *rq1,
    struct runqueue *rq2)
{
    if (rq1 == rq2)
        spinlock(&rq1->lock);
    else {
        if (rq1 < rq2) {
            spin_lock(&rq1->lock);
            spin_lock(&rq2->lock);
        } else {
            spin_lock(&rq2->lock);
            spin_lock(&rq2->lock);
            spin_lock(&rq2->lock);
            spin_lock(&rq1->lock);
            spin_lock(&rq1->lock);
            }
        }
}
```

Why not?

Р2

```
double_rq_lock(struct runqueue *rq1,
       struct runqueue *rq2)
         spin lock(&rq1->lock);
         spin lock(&rq2->lock);
     }
struct runqueue *RdQ, *DevQ1, *DevQ2, ...
```

```
Р1
double rq lock(RdQ,DevQ1);
                             double rq lock(DevQ1,RdQ);
```

double_rq_unlock() in Linux Kernel

```
double_rq_unlock(struct runqueue *rq1,
  struct runqueue *rq2)
{
  spin unlock(&rq1->lock);
     if (rq1 != rq2)
          spin unlock(&rq2->lock);
```

Pthread Semaphore

- Pthread semaphores for multi-threaded programming in Unix/Linux:
 - Pthread Mutex Lock (binary semaphore)
 - Pthread Semaphore (general counting semaphore)

Pthread Mutex Lock

```
#include <pthread.h>

/*declare a mutex variable*/

pthread_mutex_t mutex;

/* create a mutex lock */

pthread_mutex_init (&mutex, NULL);

/* acquire the mutex lock */

pthread_mutex_lock(&mutex);

/* release the mutex lock */

pthread_mutex_unlock(&mutex);
```

Using Pthread Mutex Locks

Use mutex locks to solve critical section problems:

```
#include <pthread.h>
pthread_mutex_t mutex ;
...
pthread_mutex_init(&mutex, NULL) ;
...
pthread_mutex_lock(&mutex) ;
/*** critical section ***/
pthread_mutex_unlock(&mutex) ;
```

Pthread Semaphores

```
#include <semaphore.h>

/*declare a pthread semaphore*/
sem_t sem;

/* create and initialize a semaphore */
sem_init (&sem, flag, initial_value);

/* wait() operation */
sem_wait(&sem);

/* signal() operation */
sem_post(&sem);
```

Using Pthread semaphore

Using Pthread semaphores for counters shared by multiple threads:

```
#include <semaphore.h>
sem_t counter;
...
sem_init(&counter, 0, 0); /* initially 0 */
...
sem_post(&counter); /* increment */
...
sem_wait(&counter); /* decrement */
```

volatile in multithread program

In multithread programming, a shared global variable must be declared as volatile to avoid compiler's optimization which may cause conflicts:

```
volatile int data ;
volatile char buffer[100] ;
```

Process Synchronization for multiple processes in Unix

 In Unix, a shared global variable must be created with the following systems calls:

```
#include <sys/shm.h>
int shmget(key_t key, size_t size, int shmflg);

void *shmat(int shmid, const void *shmaddr, int shmflg);
int shmdt(const void *shmaddr);
int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

nanosleep()
