CSE 3221.3 Operating System Fundamentals

No.6

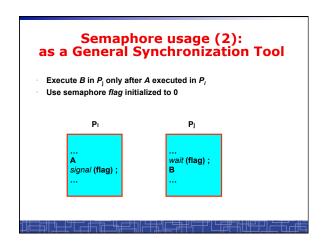

Process Synchronization(2)

Prof. Hui Jiang Dept of Computer Science and Engineering York University

Semaphores Problems with the software solutions. - Complicated programming, not flexible to use. - Not easy to generalize to more complex synchronization problems. Semaphore (a.k.a. lock): an easy-to-use synchronization tool - An integer variable S - wait(S) { while (S<=0); S--; } - signal(S) { S++; }

Semaphore usage (1): the n-process critical-section problem The n processes share a semaphore, Semaphore mutex; // mutex is initialized to 1. Process Pi do { wait(mutex); critical section of Pi

signal(mutex); remainder section of Pi while (1);

Spinlock vs. Sleeping Lock

- Previous definition of semaphore requires busy waiting.
 - It is called spinlock.
 - spinlock does not need context switch, but waste CPU cycles in a continuous loop.
 - spinlock is OK only for lock waiting is very short.
- Semaphore without busy-waiting, called sleeping lock:
 - In defining wait(), rather than busy-waiting, the process makes system calls to block itself and switch back to waiting state, and put the process to a waiting queue associated with the semaphore. The control is transferred to CPU scheduler.
 - In defining signal(), the process makes system calls to pick a process in the waiting queue of the semaphore, wake it up by moving it to the ready queue to wait for CPU scheduling.
 - Sleeping Lock is good only for long waiting.

Spinlock Implementation(1) In uni-processor machine, disabling interrupt before modifying semaphore. if(**S**>0) { S++; return ; return; while(1);

```
Spinlock Implementation(2)

In multi-processor machine, inhibiting interrupt of all processors is not easy and efficient.

Use software solution to critical-section problems

- e.g., bakery algorithm.

- Treat wait() and signal() as critical sections.

Or use hardware support if available:

- TestAndSet() or Swap()

Example: implement spinlock among two processes.

- Use Peterson's algorithm for protection.

- Shared data:

Semaphore S; Initially S=1

boolean flag[2]; initially flag [0] = flag [1] = false.
int turn; initially turn = 0 or 1.
```

Spinlock Implementation(3) wait(S) { int i=process_ID(); II<mark>0→P0, 1→P1</mark> int i=process_ID(); II0 \rightarrow P0, 1 \rightarrow P1 int j=(i+1)%2; int j=(i+1)%2 flag [i]:= true; //request to enter flag [i]:= true; //request to enter turn = j; while (flag [j] and turn = j) ; while (flag [j] and turn = j); if (S >0) { //critical section S++; //critical section flag [i] = false; return ; flag [i] = false; } else { flag [i] = false; return: } while (1);

```
Spinlock Implementation(2)

In multi-processor machine, inhibiting interrupt of all processors is not easy and efficient.

Use software solution to critical-section problems

- e.g., bakery algorithm.

- Treat wait() and signal() as critical sections.

Or use hardware support if available:

- TestAndSet() or Swap()

Example: implement spinlock between N processes.

- Use Bakery algorithm for protection.

- Shared data:

Semaphore S; Initially S=1

boolean choosing[N]; (Initially false)
int number[N]; (Initially 0)
```

```
Spinlock Implementation(3)
 int i=process ID():
                                                                      int i=process_ID();
  choosing[i] = true;
 cnossing[ ] = tmx(number[0], number[1], ..., number [N - 1])+1; choosing[ i ] = false; for (j = 0; j > N; j++) { while (choosing[ j ]);
                                                                    choosing[ i ] = true;
                                                                    number[ i ] = max(number
..., number [N - 1])+1;
choosing[ i ] = false;
for (j = 0; j < N; j++) {
                                                                                               ımber[0], number[1],
    while (choosing[]]);
while ((number[j]]!= 0) &&
    (number[j]])< (number[i]]i));
                                                                         if (S >0) { //critical section
                                                                     S++; //critical section
  number[i] = 0;
   return ;
                                                                     number[i] = 0;
                                                                     return
while (1);
```

Sleeping Lock (I) Define a sleeping lock as a structure: typedef struct { int value; // Initialized to 1 struct process *L; } semaphore; Assume two system calls: - block() suspends the process that invokes it. - wakeup(P) resumes the execution of a blocked process P. Equally applicable to multiple threads in one process.

Sleeping Lock (II)

Semaphore operations now defined as:

Two Types of Semaphores: Binary vs. Counting

- Binary semaphore (a.k.a. mutex lock) integer value can range only between 0 and 1; simpler to implement by hardware.
- · Counting semaphore integer value can range over an unrestricted domain.
- We can implement a counting semaphore S by using two binary semaphore.
- · Binary semaphore is normally used as mutex lock.
- · Counting semaphore can be used as shared counter, load controller, etc...

Implementing counting semaphore with two Binary Semaphores

Data structures:

binary-semaphore S1, S2;

int C:

Initialization:

S1 = 1S2 = 0

C = initial value of semaphore S

Implementing S

wait(S) operation:

wait_binary(S1);
C--;
if (C < 0) {
 signal_binary(S1);
 wait_binary(S2);
}
signal_binary(S1);</pre>

signal(S) operation:

Classical Synchronization Problems

- The Bounded-Buffer P-C Problem
- The Readers-Writers Problem
- The Dining-Philosophers Problem

Bounded-Buffer P-C Problem

- A producer produces some data for a consumer to consume. They share a bounded-buffer for data transferring.
- · Shared memory:

A buffer to hold at most *n* items

Shared data (three semaphores)

Semaphore filled, empty; /*counting*/
Semaphore mutex; /* binary */

Initially:

filled = 0, empty = n, mutex = 1

Bounded-Buffer Problem: Producer Process do { produce an item in nextp wait(empty); wait(empty); wait(mutex); add nextp to buffer signal(mutex); signal(filled); } while (1);

```
Bounded-Buffer Problem:
Consumer Process

do {
    wait(filled)
    wait(mutex);
    ...
    remove an item from buffer to nextc
    ...
    signal(mutex);
    signal(empty);
    ...
    consume the item in nextc
    ...
} while (1);
```

The Readers-Writers Problem

- Many processes concurrently access a data object
 - Readers: only read the data.
 - Writers: update and may write the data object.
- Only writer needs exclusive access of the data.
- The first readers-writers problem:
 - Unless a writer has already obtained permission to use the shared data, readers are always allowed to access data.
 - May starve a writer.
- The second readers-writer problem:
 - Once a writer is ready, the writer performs its write as soon as possible.
 - May starve a reader.

The 1st Readers-Writers Problem

Use semaphore to implement 1st readers-writer problem

Shared data:

Semaphore mutex = 1; // mutually exclusive access to // readcount among readers

Semaphore wrt = 1; // mutual exclusion to the data object // used by every writer

//also set by the 1st reader to read the data
// and clear by the last reader to finish reading

The 1st Readers-Writers Problem

Writer Process

... wait(wrt);

signal(wrt);

writing is performed

Reader Process

...
wait(mutex);
readcount++;
if (readcount == 1) wait(wrt);
signal(mutex);
...

reading is performed
...
wait(mutex):

readcount--; if (readcount == 0) signal(wrt); signal(mutex);

<u>╣╫┸╫┸┸╫</u>

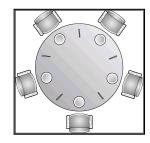

The Dining-Philosophers Problem

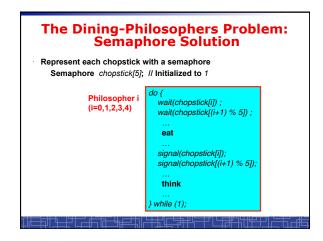

Five philosophers are thinking or eating Using only five chopsticks

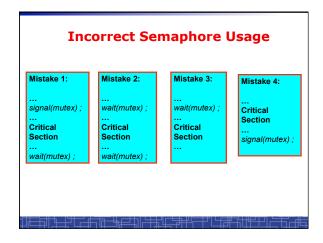

When thinking, no need for chopsticks.

When eating, need two closest chopsticks.
Can pick up only one

chopsticks
Can not get the one already in the hand of a neighbor.

```
double_rq_lock()
in Linux Kernel

double_rq_lock(struct runqueue *rq1,
    struct runqueue *rq2)
{
    if (rq1 == rq2)
        spinlock(&rq1->lock);
    else {
        if (rq1 < rq2) {
            spin_lock(&rq2->lock);
            spin_lock(&rq2->lock);
        } else {
            spin_lock(&rq2->lock);
            spin_lock(&rq2->lock);
        } spin_lock(&rq1->lock);
        }
}
```

```
why not?

double_rq_lock(struct runqueue *rq1,
    struct runqueue *rq2)
{
    spin_lock(&rq1->lock);
    spin_lock(&rq2->lock);
}

struct runqueue *RdQ, *DevQ1, *DevQ2, ...

P1
    double_rq_lock(RdQ,DevQ1);
    double_rq_lock(DevQ1,RdQ);
    ...
```

Pthread Semaphore

- Pthread semaphores for multi-threaded programming in Unix/Linux:
 - Pthread Mutex Lock (binary semaphore)
 - Pthread Semaphore (general counting semaphore)

Pthread Mutex Lock

```
#include <pthread.h>
/*declare a mutex variable*/
pthread_mutex_t mutex;

/* create a mutex lock */
pthread_mutex_init (&mutex, NULL);

/* acquire the mutex lock */
pthread_mutex_lock(&mutex);

/* release the mutex lock */
pthread_mutex_unlock(&mutex);
```

Using Pthread Mutex Locks

· Use mutex locks to solve critical section problems:

```
#include <pthread.h>
pthread_mutex_t mutex ;
...
pthread_mutex_init(&mutex, NULL) ;
...
pthread_mutex_lock(&mutex) ;
/*** critical section ***/
pthread_mutex_unlock(&mutex) ;
```

Pthread Semaphores

```
#include <semaphore.h>

/*declare a pthread semaphore*/
sem_t sem;

/* create and initialize a semaphore */
sem_init (&sem, flag, initial_value);

/* wait() operation */
sem_wait(&sem);

/* signal() operation */
sem_post(&sem);
```

Using Pthread semaphore

Using Pthread semaphores for counters shared by multiple threads:

```
#include <semaphore.h>
sem_t counter;
...
sem_init(&counter, 0, 0); /* initially 0 */
...
sem_post(&counter); /* increment */
...
sem_wait(&counter); /* decrement */
```

volatile in multithread program

In multithread programming, a shared global variable must be declared as volatile to avoid compiler's optimization which may cause conflicts:

```
volatile int data ;
volatile char buffer[100] ;
```

Process Synchronization for multiple processes in Unix

In Unix, a shared global variable must be created with the following systems calls:

```
#include <sys/shm.h>
int shmget(key_t key, size_t size, int shmflg);

void *shmat(int shmid, const void *shmaddr, int shmflg);
int shmdt(const void *shmaddr);
int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

nanosleep()
