Subnets

- Network divided into several smaller subnetworks each having its own subnetwork address
 - Internally, each subnetwork is recognized by its subnetwork address; to the rest of the Internet all subnetoworks still appear as a single network
- Organization of address space in a subnetted network
 - A number of HostID bits are borrowed for subnet identification
 - •With m borrowed bits, 2^m subnets can be created
 - Number of hosts in each subnet: 2^{Hostid-m}

-48

Benefits of subnets

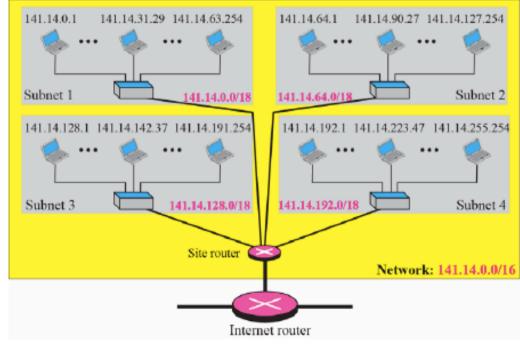

Class B network before subnetting: each packet flooded through entire network. 2-level routing hierarchy:

- (1) deliver to the network
- (2) deliver to the host

Class B network after subnetting: packets routed only to appropriate network segment. 3-level routing hierarchy:

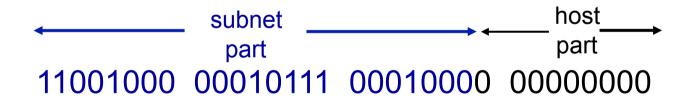

- (1) deliver to the network
- (2) deliver to the subnetwork
- (3) deliver to the host

Classless addressing: CIDR

CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: a.b.c.d/x, where x is # bits in subnet portion of address

200.23.16.0/23

IP addresses: how to get one?

Q: How does a host get IP address?

- hard-coded by system admin in a file
 - Windows: control-panel->network->configuration->tcp/ ip->properties
 - UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from as server
 - "plug-and-play"

DHCP: Dynamic Host Configuration Protocol

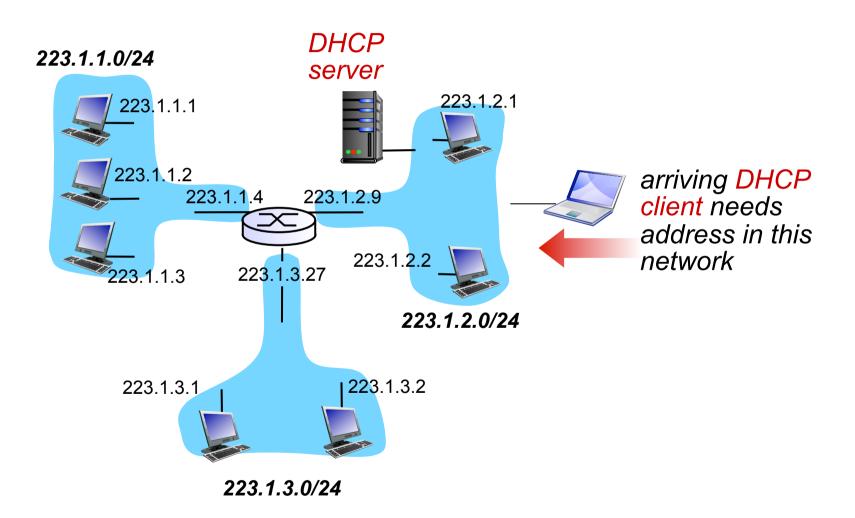

goal: allow host to dynamically obtain its IP address from network server when it joins network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network (more shortly)

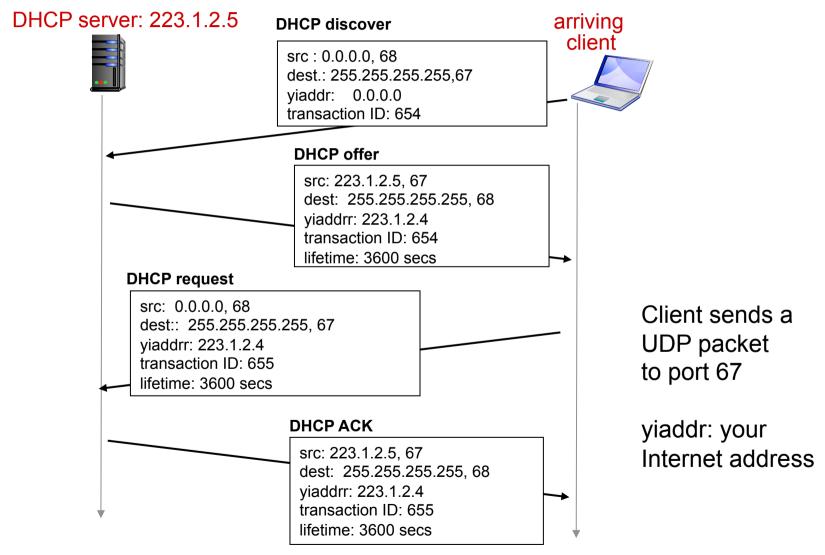

DHCP overview:

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

DHCP client-server scenario

DHCP client-server scenario

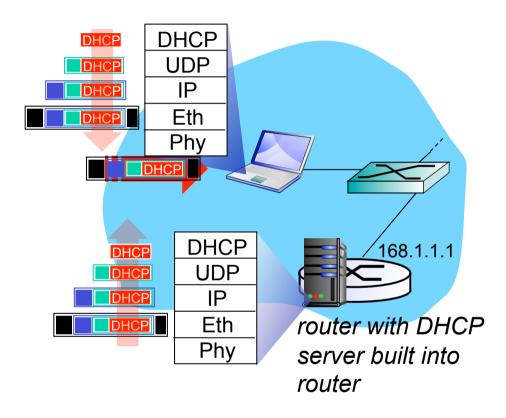

DHCP: more than IP addresses

DHCP can return more than just allocated IP address on subnet:

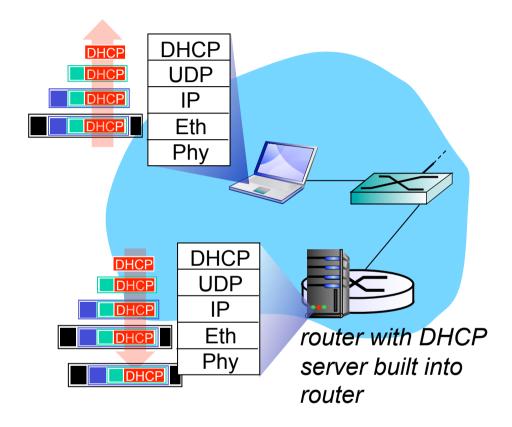

- address of first-hop router for client
- name and IP address of DNS sever
- network mask (indicating network versus host portion of address)

DHCP: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802. I Ethernet
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

DHCP: example

- DHCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to DHCP at client
- client now knows its IP address, name and IP address of DSN server, IP address of its first-hop router

IP addresses: how to get one?

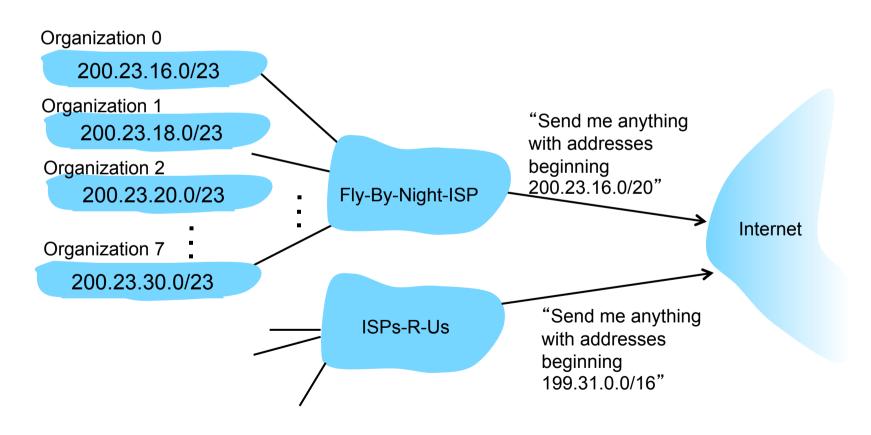

Q: how does network get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	11001000	00010111	00010000	00000000	200.23.16.0/20
Organization 0	11001000	00010111	0001000	0000000	200.23.16.0/23
Organization 1	·				200.23.18.0/23
Organization 2					200.23.20.0/23
•••					••••
Organization 7	11001000	00010111	00011110	00000000	200.23.30.0/23

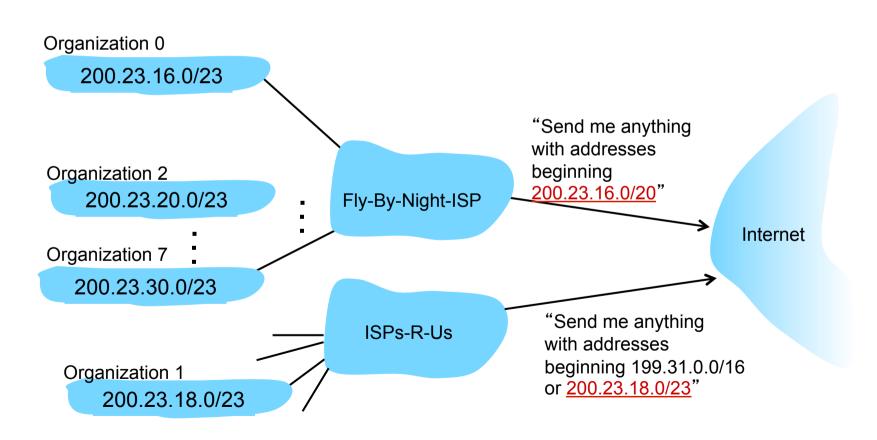

Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

Hierarchical addressing: more specific routes

ISPs-R-Us has a more specific route to Organization I

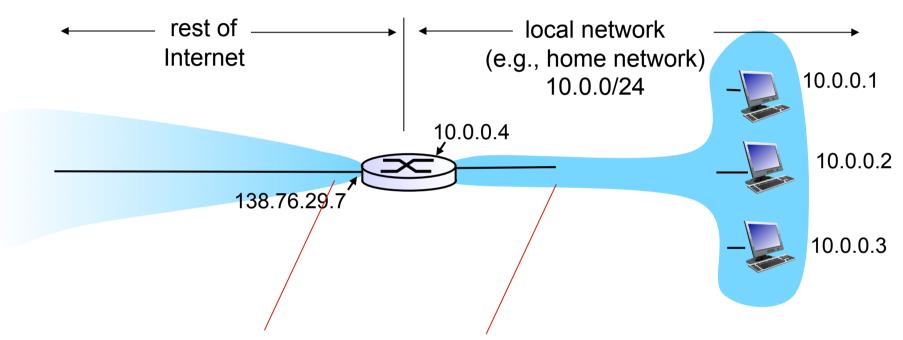

IP addressing: the last word...

Q: how does an ISP get block of addresses?

A: ICANN: Internet Corporation for Assigned Names and Numbers http://www.icann.org/

- allocates addresses
- manages DNS
- assigns domain names, resolves disputes

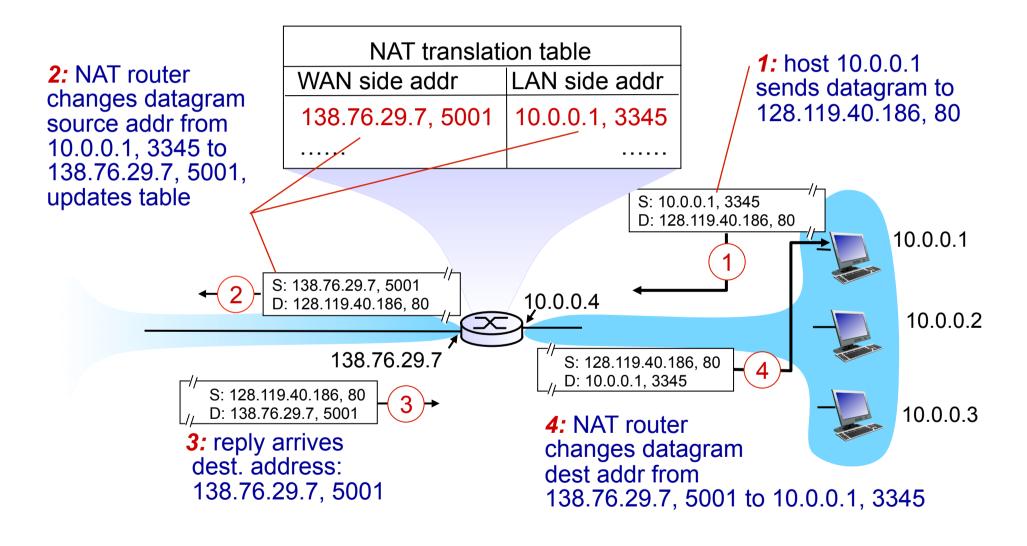

all datagrams leaving local network have same single source NAT IP address: 138.76.29.7, different source port numbers datagrams with source or destination in this network have 10.0.0/24 address for source, destination (as usual)

motivation: local network uses just one IP address as far as outside world is concerned:

- range of addresses not needed from ISP: just one IP address for all devices
- can change addresses of devices in local network without notifying outside world
- can change ISP without changing addresses of devices in local network
- devices inside local net not explicitly addressable, visible by outside world (a security plus)

implementation: NAT router must:

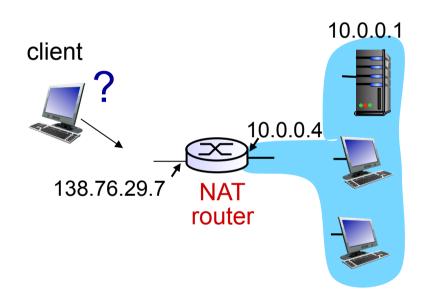

- outgoing datagrams: replace (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
 - ... remote clients/servers will respond using (NAT IP address, new port #) as destination addr
- remember (in NAT translation table) every (source IP address, port #) to (NAT IP address, new port #) translation pair
- incoming datagrams: replace (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

- 16-bit port-number field:
 - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
 - routers should only process up to layer 3
 - violates end-to-end argument
 - NAT possibility must be taken into account by app designers, e.g., P2P applications
 - address shortage should instead be solved by IPv6

NAT traversal problem

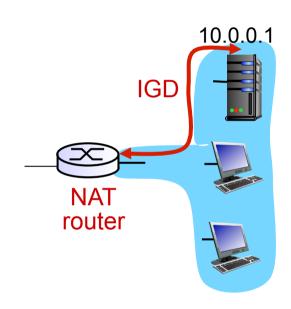

- client wants to connect to server with address 10.0.0.1
 - server address [0.0.0.] local to LAN (client can't use it as destination addr)
 - only one externally visible NATed address: 138.76.29.7
- solution I: statically configure NAT to forward incoming connection requests at given port to server
 - e.g., (123.76.29.7, port 2500)
 always forwarded to 10.0.0.1 port 25000

NAT traversal problem

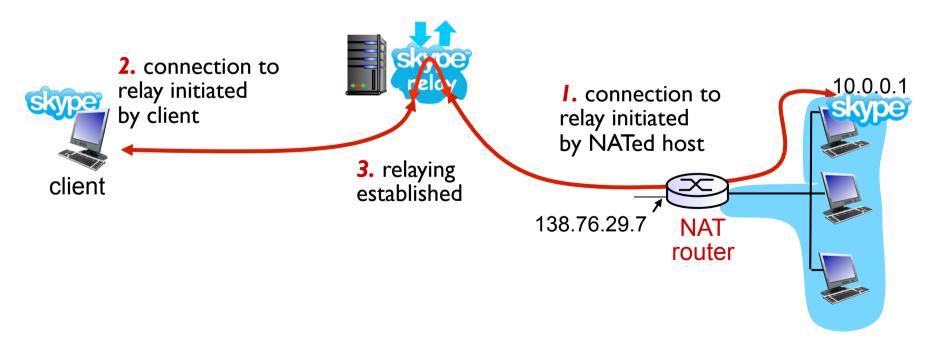

- solution 2: Universal Plug and Play (UPnP) Internet Gateway Device (IGD) Protocol. Allows NATed host to:
 - learn public IP address (138.76.29.7)
 - add/remove port mappings (with lease times)

i.e., automate static NAT port map configuration

NAT traversal problem

- solution 3: relaying (used in Skype)
 - NATed client establishes connection to relay
 - external client connects to relay
 - relay bridges packets between to connections

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

- 4.5 routing algorithms
 - link state
 - distance vector
 - hierarchical routing
- 4.6 routing in the Internet
 - RIP
 - OSPF
 - BGP
- 4.7 broadcast and multicast routing

ICMP: internet control message protocol

Why ICMP?

- Lack of error control, e.g. error-reporting and error correcting, and network assistance mechanisms
- What if a router must discard a datagram because the datagram's TTL=0?
- What if the final host must discard a number of fragments because it has not received all fragments by a certain time?
- What is a host needs to determine if another host/router is alive?
- ICMP "companion" to IP, intend to compensate for IP deficiencies
 - IP header's "protocol field" set to 1 if the packet carries an ICMP message

ICMP: internet control message protocol

*	used by hosts & routers	T	O = al =	
	to communicate network-	<u>rype</u>	Code	description
		0	0	echo reply (ping)
	level information	3	0	dest. network unreachable
	error reporting:	3	1	dest host unreachable
	unreachable host, network,	3	2	dest protocol unreachable
	port, protocol	3	3	dest port unreachable
	echo request/reply (used by	3	6	dest network unknown
	ping)	3	7	dest host unknown
*	network-layer "above" IP:	4	0	source quench (congestion
	 ICMP msgs carried in IP 			control - not used)
	datagrams	8	0	echo request (ping)
		9	0	route advertisement
**	ICMP message: type, code	10	0	router discovery
	plus first 8 bytes of IP	11	0	TTL expired
	datagram causing error	12	0	bad IP header

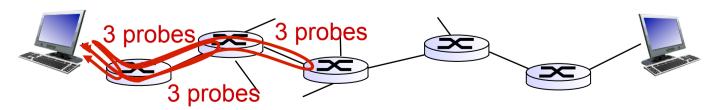

Traceroute and ICMP

- source sends series of UDP segments to dest
 - first set has TTL = I
 - second set has TTL=2, etc.
 - unlikely port number
- when nth set of datagrams arrives to nth router:
 - router discards datagrams
 - and sends source ICMP messages (type II, code 0)
 - ICMP messages includes name of router & IP address

 when ICMP messages arrives, source records RTTs

stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

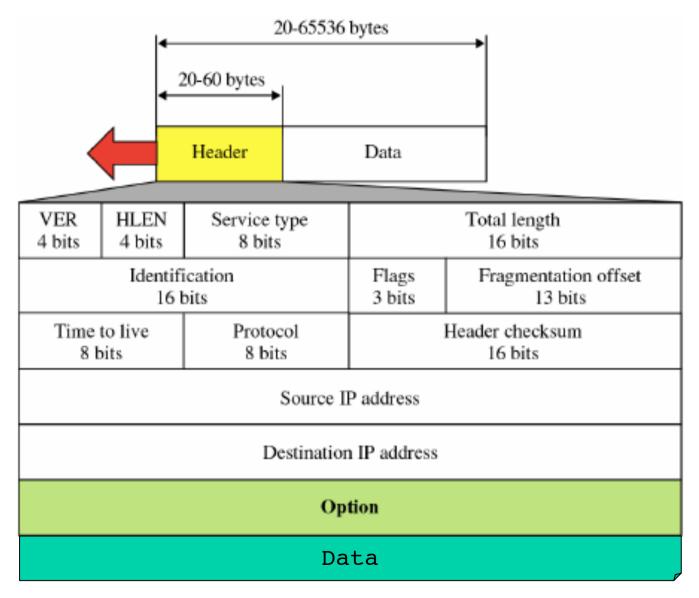

IPv6: motivation

- initial motivation: 32-bit address space soon to be completely allocated.
- additional motivation:
 - header format helps speed processing/forwarding
 - header changes to facilitate QoS

IPv6 datagram format:

- expanded addressing capability: 128-bit address
- fixed-length 40 byte header
- no fragmentation allowed

IPv4 datagram format

IPv6 datagram format

A streamlined 40-byte header:

- •traffic class: identify priority among datagrams in flow
- •flow Label: identify datagrams in same "flow."
- •next header: identify upper layer protocol for data

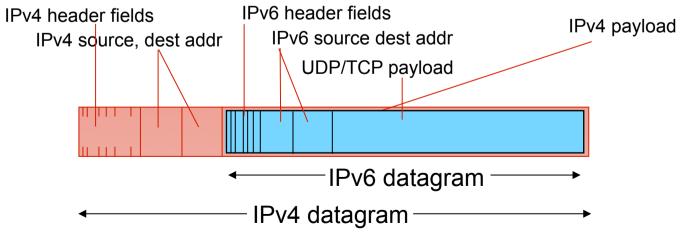

ver	traff	flow label			
payload len		next hdr	hop limit		
source address (128 bits)					
destination address (128 bits)					
data					
← 32 bits —					

Other changes from IPv4

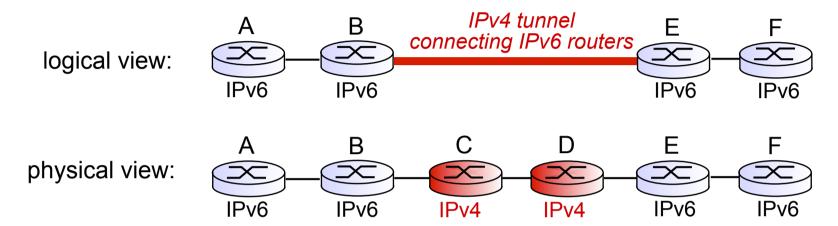

- checksum: removed entirely to reduce processing time at each hop
- options: allowed, but outside of header, indicated by "Next Header" field
- ❖ ICMPv6: new version of ICMP
 - additional message types, e.g. "Packet Too Big"
 - multicast group management functions

Transition from IPv4 to IPv6

- not all routers can be upgraded simultaneously
 - no "flag days"
 - how will network operate with mixed IPv4 and IPv6 routers?
- tunneling: IPv6 datagram carried as payload in IPv4 datagram among IPv4 routers

Tunneling

Tunneling
