

Non-reentrant C code

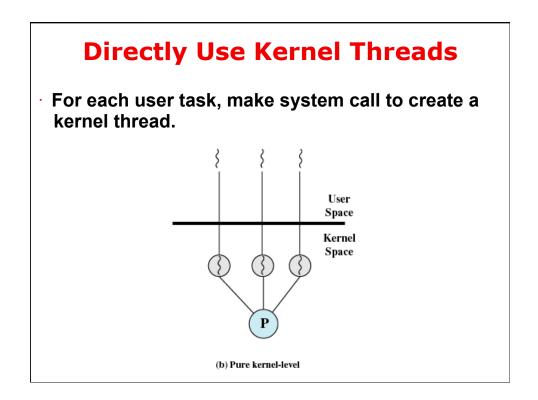

```
int delta;
int diff (int x, int y)
{
    delta = y - x;
    if (delta < 0) delta = -delta;
    return delta;
}
```

Reentrant C code

```
int diff (int x, int y)
{
    int delta;

    delta = y - x;
    if (delta < 0) delta = -delta;
    return delta;
}</pre>
```

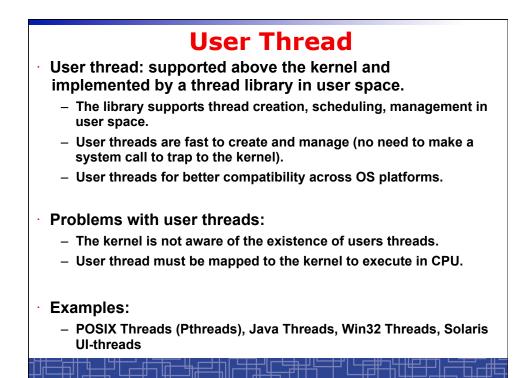

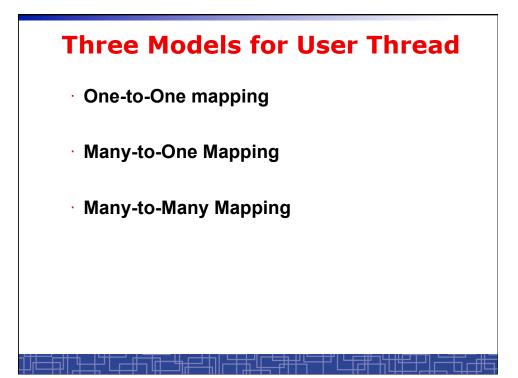

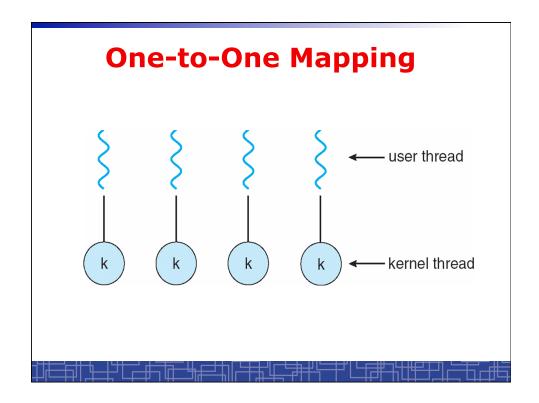

Example of Kernel Thread: Linux Thread

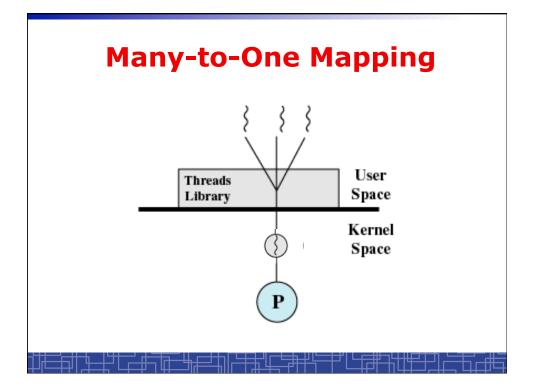

- · Linux kernel support kernel threads, system call clone().
- fork() creates a new process
 - Create a new memory space for new process
 - Copy from the address space of the calling process
- clone() simulates fork(), but
 - It does not create new memory space.
 - The new process shares the same address space of the original process.
 - → two processes sharing the same memory space. (something like thread)

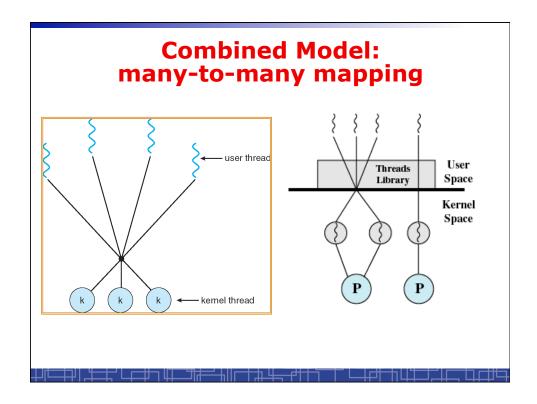

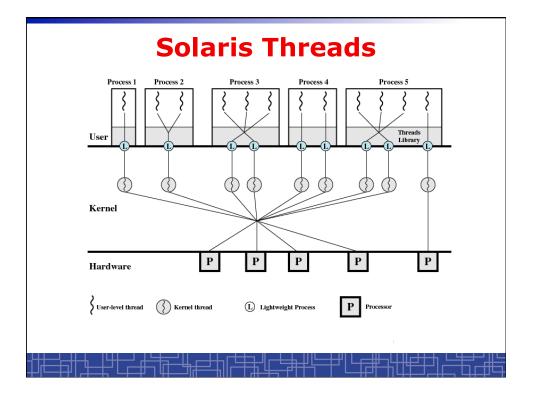

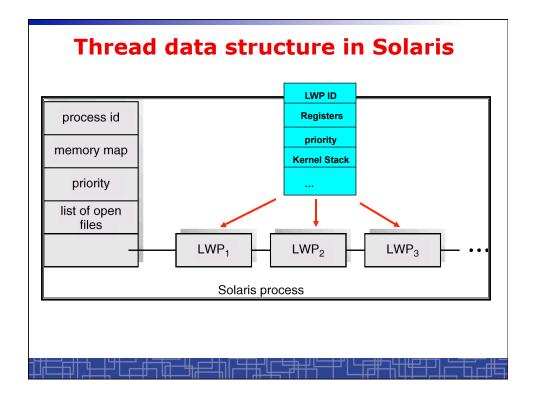

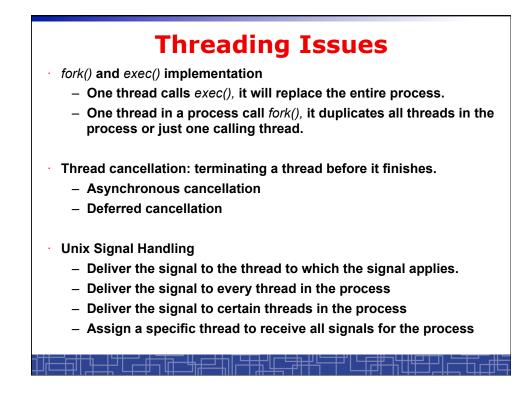

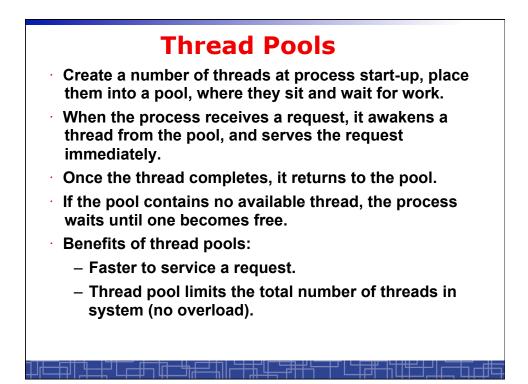

Three Models to use Threads
Pipeline
 Assembly line: each thread repeatedly performs the same operation on a sequence of data sets, passing each result to another thread for next step.
· Work Crew
 Each thread performs an operation on its own data independently, then combine all results to get the final.
Client/Server
 A client contacts with an independent server for each job.
