

# **Bandpass Modulation**

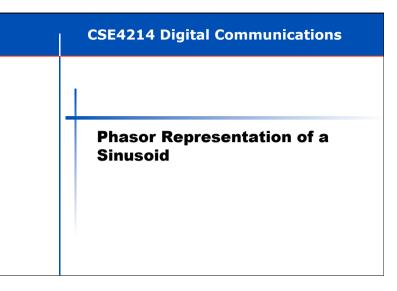

- Baseband transmission is conducted at low frequencies
- Passband transmission is to send the signal at high frequencies
  - Signal is converted to a sinusoidal waveform, e.g.  $s(t) = A(t)\cos[\omega_0 t + \phi(t)]$

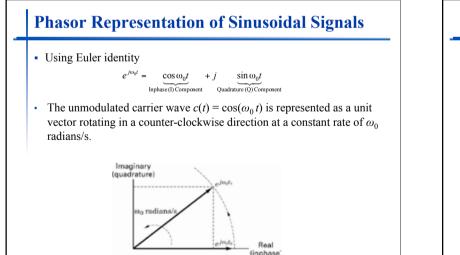

where  $\omega_0$  is called carrier frequency is much higher than the highest frequency of the modulating signals, i.e. messages

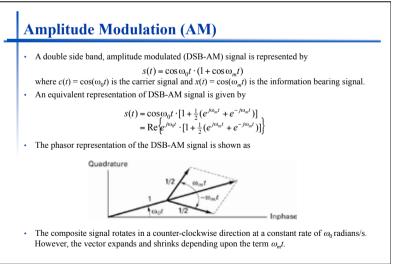

Bits are encoded as a variation of the amplitude, phase, frequency, or some combination of these parameters.

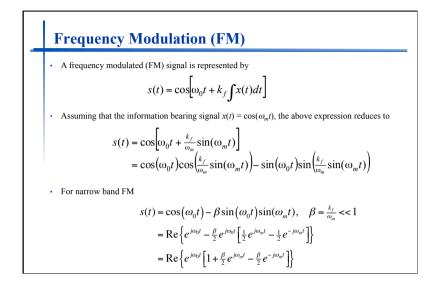

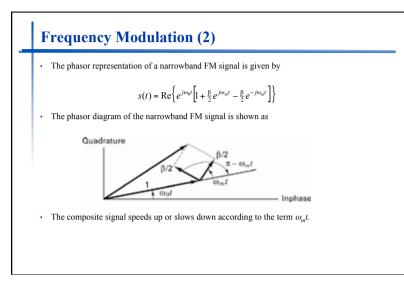

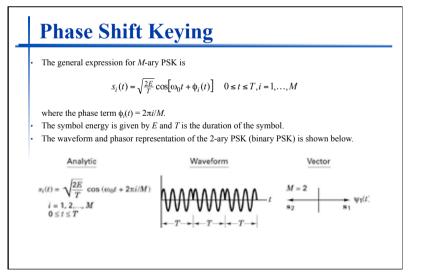

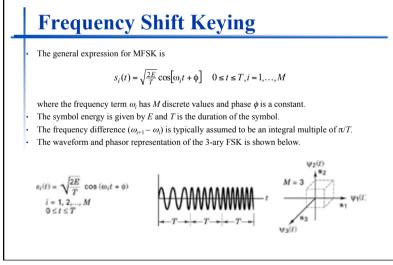

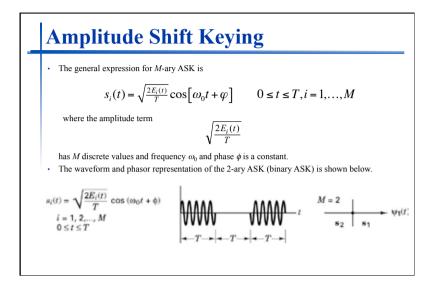

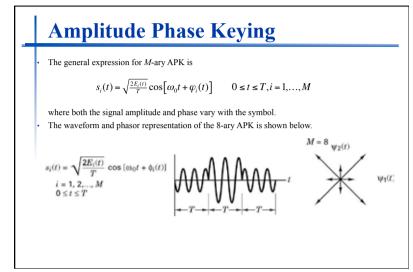

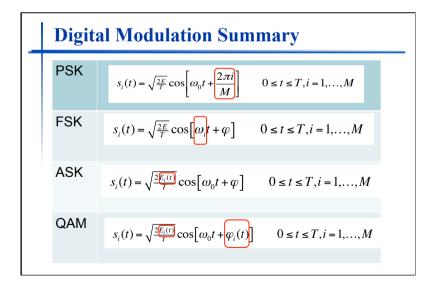

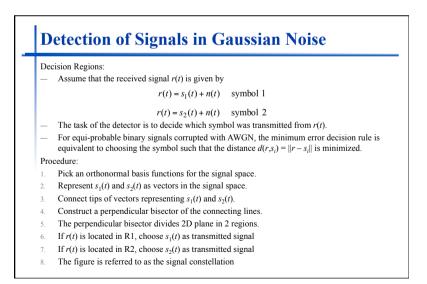

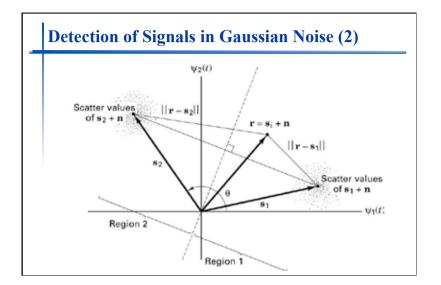

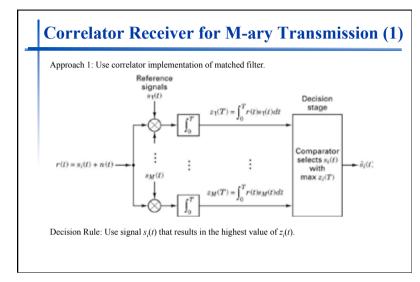

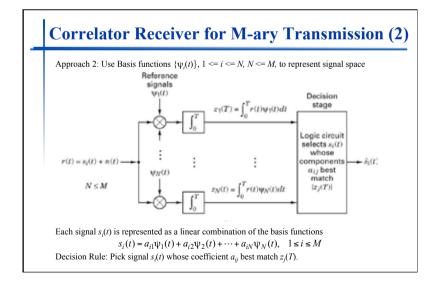

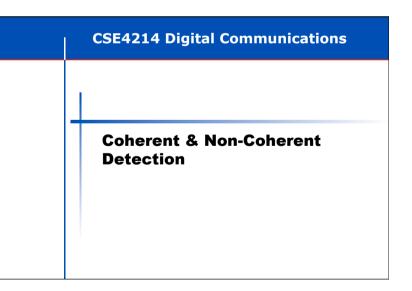

## Definitions

- Coherent detection the receiver exploits knowledge of the carrier's phase to detect the signal
- Require expensive and complex carrier recovery circuit
- Better bit error rate of detection
- Non-coherent detection the receiver does not utilize phase reference information
  - Do not require expensive and complex carrier recovery circuit
  - Poorer bit error rate of detection
  - Differential systems have important advantages and are widely used in practice
    <sup>21</sup>

## **Coherent Receiver**

- Carrier recovery for demodulation
  - Received signal  $r(t) = A\cos(\omega_c t + \varphi) + n(t)$
  - Local carrier  $\cos(\omega_c t + \hat{\varphi})$
  - Carrier recovery phase lock loop circuit

 $\Delta \varphi = \varphi - \hat{\varphi} \rightarrow 0$ 

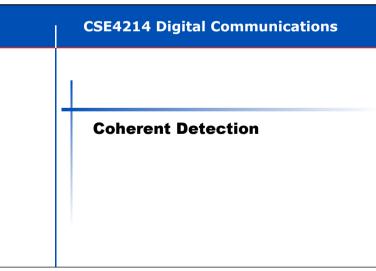

Demodulation leads to recovered baseband signal

 $Y(t) = s(t + \tau) + n(t)$ 

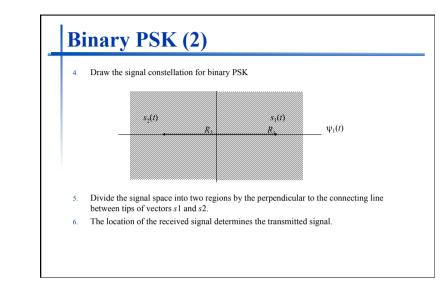

- Timing recovery for sampling
  - Align receiver clock with transmitter clock, so that sampling  $\rightarrow$  no ISI

 $Y_k = s_k + n_k$ 

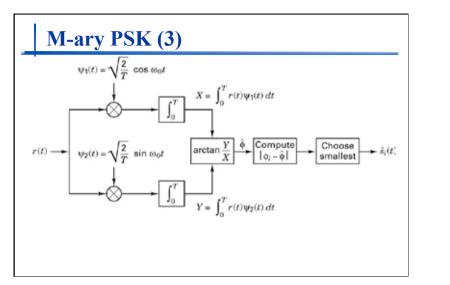

## Non-Coherent Receiver • No carrier recovery for demodulation • Received signal $r(t) = A \cos(\omega_c t + \varphi) + n(t)$ • Local carrier $\cos(\omega_c t + \hat{\varphi})$ • No carrier recovery $\Delta \varphi = \phi = \varphi - \hat{\varphi} \neq 0$ • Demodulation leads to recovered baseband signal $Y(t) = s(t + \tau)e^{j\phi} + n(t)$ • Timing recovery for sampling • Align receiver clock with transmitter clock, sampling results in $Y_k = s_k e^{i\phi} + n_k$ could not recover transmitted symbols properly from $Y_k$

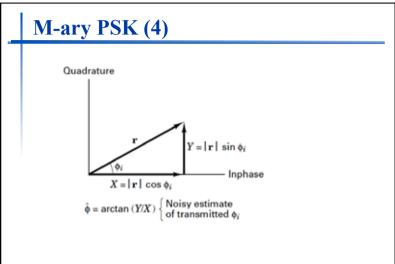

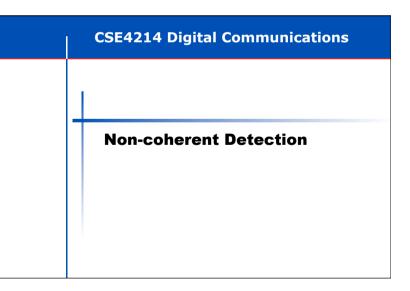

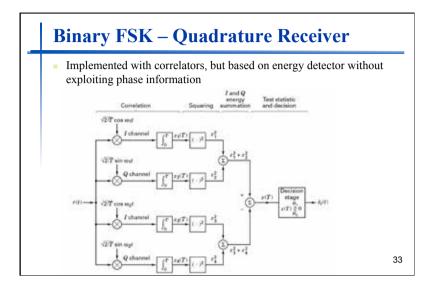

# **FSK** • A typical set of FSK is described by: $s_{i}(t) = \sqrt{\frac{2E}{T}} \cos\left[\omega_{i}t + \varphi\right] \qquad 0 \le t \le T, i = 1, ..., M$ *E* is the energy content of $s_{i}(t)$ over each symbol duration *T*, and $(\omega_{i+1}-\omega_{i})$ is typically assumed to be an integral multiple of $\pi/T$ . The phase term is an arbitrary constant and can be set equal to zero. • Assume that basis functions form an orthonormal set, i.e. $\psi_{i}(t) = \sqrt{\frac{2}{T}} \cos(\omega_{i}t) \int \frac{2}{T} \cos(\omega_{j}t) dt = \begin{cases} \sqrt{E} & \text{for } i = j \\ 0 & \text{otherwise} \end{cases}$

#### **FSK – Envelope Detector** Implemented with bandpass filters followed by envelope detectors. • Envelope detector consists of a rectifier and a lowpass filter Bandpass filters centered at $f_i$ with bandwidth $W_f = 1/T$ Envelope $z_1(T)$ Filter f1 detector $z_2(T)$ Filter Envelope Decision $r_i(t) = s_i(t) + n(t) \rightarrow \hat{s}_i(t)$ f2 detector stage Envelope $z_M(T)$ Filter fм detector 34

## **Minimum Tone Spacing for Orthogonal FSK**

- FSK is usually implemented as orthogonal signaling.
- Not all FSK signaling is orthogonal, how can we tell if the tone in a signaling set form an orthogonal set?
  - To form an orthogonal set, they must be uncorrelated over a symbol time *T*
- Minimum tone spacing for orthogonal FSK:
  - *Any pair of tones in the set must have a frequency separation that is a multiple of 1/T hertz*

# Activity 1

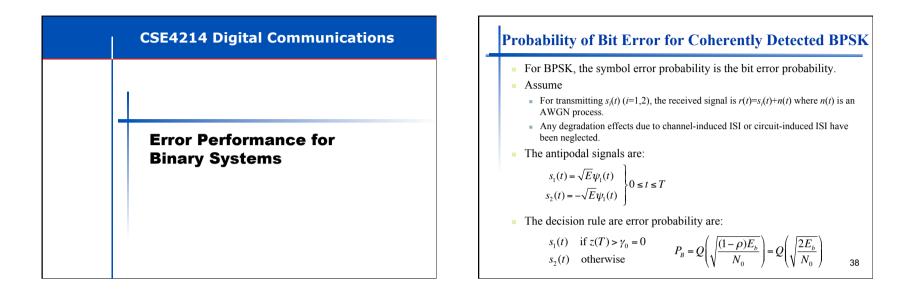

Consider two waveforms  $\cos(2\pi f_1 t + \phi)$  and  $\cos(2\pi f_2 t)$ 

to be used for non-coherent FSK-signaling, where  $f_1 > f_2$ . The symbol rate is equal to 1/T symbols/s, where *T* is the symbol duration and  $\phi$  is a constant arbitrary angle from 0 to  $2\pi$ .

Prove that the minimum tone spacing for non-coherent detected orthogonal FSK signaling is 1/T.

35

# Activity 2

Find the bit error probability for a BPSK system with a bit rate of 1Mbit/s. The received waveforms  $s_1(t) = A \cos \omega_0 t$  and  $s_2(t) = -A \cos \omega_0 t$  are coherently detected with a matched filter. The value of A is 10mV. Assume that the single-sided noise power spectral density is  $N_0=10^{-11}$  W/Hz and that signal power and energy per bit are normalized relative to a 1 ohm load.

## Probability of Bit Error for Coherently Detected BFSK

- For BFSK, the symbol error probability is the bit error probability.
- Assume
  - For transmitting  $s_i(t)$  (*i*=1,2), the received signal is  $r(t)=s_i(t)+n(t)$  where n(t) is an AWGN process.
  - Any degradation effects due to channel-induced ISI or circuit-induced ISI have been neglected.
- For orthogonal signals are:

$$\begin{cases} s_1(t) = A\cos\omega_0 t \\ s_2(t) = A\cos\omega_1 t \end{cases} \begin{cases} 0 \le t \le T \end{cases}$$

 $P_{B} = Q\left(\sqrt{\frac{(1-\rho)E_{b}}{N_{0}}}\right) = Q\left(\sqrt{\frac{E_{b}}{N_{0}}}\right)$ 

• The error probability is:
