

Boundary Value Testing

Chapter 5

- ## Introduction
- Input domain testing is the most commonly taught (and perhaps the most commonly used) software testing technique
 - We will see a number of approaches to boundary value analysis
 - We will then study some of the limitations of domain testing

- ## Boundary Value Analysis
- Many programs can be viewed as a function F that maps values from a set A (its domain) to values in another set B (its range)

$$F : A \rightarrow B$$
 - The input variables of F will have some (possibly unstated) boundaries:

$$a \leq x_1 \leq b \quad c \leq x_2 \leq d$$

- ## Boundary value analysis
- For each variable, select five values
 - Minimum
 - Just above the minimum
 - Nominal
 - Just below the maximum
 - Maximum

- ## Single fault assumption
- Failures are only rarely the result of the simultaneous occurrence of two (or more) faults
 - Generate test cases as such for all i
 - Values of all but one variable x_i at nominal
 - x_i assumes all 5 values from previous slide
 - What is the number of test cases?

- ## Two-variable function test cases
- | | |
|---------------------------------------|---------------------------------------|
| $\langle X_{1nom}, X_{2min} \rangle$ | $\langle X_{1min}, X_{2nom} \rangle$ |
| $\langle X_{1nom}, X_{2min+} \rangle$ | $\langle X_{1min+}, X_{2nom} \rangle$ |
| $\langle X_{1nom}, X_{2nom} \rangle$ | $\langle X_{1nom}, X_{2nom} \rangle$ |
| $\langle X_{1nom}, X_{2max-} \rangle$ | $\langle X_{1max-}, X_{2nom} \rangle$ |
| $\langle X_{1nom}, X_{2max} \rangle$ | $\langle X_{1max}, X_{2nom} \rangle$ |
- Let's apply this to the Triangle problem

Limitations

- Does not work well for boolean variables
 - We will see a more suitable approach next week
- Does not work well for logical variables
 - PIN, transaction type
- Assumes independent variables

7

Robustness testing

- A simple extension to boundary value analysis
- Add two more values per variable
 - Slightly greater than the maximum
 - Slightly less than the minimum
- What is the expected output?
 - Hopefully error message, system recovers
- Implementing these test cases may not be possible

8

Worst-Case Testing

- Rejects the simple fault assumption and tests all combinations of values
- Instead of $4n+1$ test cases, we have 5^n
- Often leads to a large number of test cases with low bug-finding power
- Usually better to apply Special Value Testing: test cases based on the tester's intuition

9

Robust Worst-Case Testing

- Add the values min- and max+ to the possible variable values
- Now take all combinations of variable values
- What is the number of test cases?

10

In class activity

- You are asked to test a software program that accepts a date as input and returns the next date
- Apply Boundary Value Analysis
- How satisfied are you with the results?

11
