Shell Programming

UNIX Shell

- The shell sits between you and the operating system, acting as a command interpreter
- The user interacts with the kernel through the shell. You can write text scripts to be acted upon by a shell
- It reads your terminal input and translates the commands into actions taken by the system. The shell is analogous to command.com in DOS
- When you log into the system you are given a default shell

UNIX Shell

- □ The original shell was the Bourne shell, sh
- Every Unix platform will either have the Bourne shell, or a Bourne compatible shell
- □ The default prompt for the Bourne shell is \$ (or #, for the root user)
- Another popular shell is C Shell. The default prompt for the C shell is %

Shell Programming

- □ Why write shell scripts?
 - To avoid repetition:
 - To do a sequence of steps with standard Unix commands over and over again so why not do it all with just one command?
 - To automate difficult tasks:
 >Many commands have difficult options to remember every time

Shell Programming

- Write shell programs by creating scripts
- A shell script is a text file with Unix commands in it
- □ First line of script starts with #! which indicates to the kernel that the script is directly executable
- #! is followed with the name of shell (spaces are allowed) to execute, using the full path name. So to set up a Bourne shell script, the first line would be:
 #!/bin/sh or
 #! /bin/sh

Shell Programming

- The first line is followed by commands
- Within the scripts # indicates a comment from that point until the end of the line.
 - #! /bin/bash # bourne again shell
 - cd tmp
 - mkdir t
- □ Specify that the script is executable by setting the proper bits on the file with chmod:
 - % chmod +x shell_script.sh
- □ To execute shell script as:
 - % ./shell_script.sh or
 - % shell_script.sh

Example Script

Hello khuwaja

	This machine is indigo The calendar for this month is								
						month	is		
#! /bin/csh	J١	uly	203	16					
echo "Hello \$USER"	Su	Мо	Tu	We	Th	Fr	Sa		
echo "This machine is `uname -n`"						1	2		
# uname - print system information	3	4	5	6	7	8	9		
# -n print network node hostname	10	11	12	13	14	15	16		
echo "The calendar for this month is:"	17	18	19	20	21	22	23		
cal	24	25	26	27	28	29	30		
echo "You are running these processes:"	31								
ns	Yo	u a:	re	runi	ning	g tl	hese	proce	sses:
20	1	PID	TT	r			TIM	E CMD	
	1	952	pt	s/30	D	00	:00:0	0 ps	
	4	894	pt	s/30	D	00	:00:1	.3 ged	it
	24	926	pt	s/30	C	00	:00:0	0 tcs	h

Variable Names

- The name of a variable can contain only letters a to z or A to Z, numbers 0 to 9 or the underscore character
- By convention, Unix Shell variables would have their names in UPPERCASE
- Examples for valid variable names _ALI TOKEN A

VAR 1

Examples for invalid variable names 2 VAR -VARIABI F VAR A!

Defining Variables

- □ Variables are defined as: variable name=variable value
- NAME="David Green"
- □ Variables of this type are called scalar variables. A scalar variable can hold only one value at a time
- □ The shell enables to store any value in a variable VAR1="Toronto" VAR2=100

Accessing Variables

- □ To access value stored in a variable, prefix its name with the dollar sign \$
- □ For example, following script would access value of defined variable NAME and would print it on STDOUT

#!/bin/sh NAME="David Green" echo \$NAME

This would produce following value David Green

Read-only Variables

- □ Shell provides a way to mark variables as readonly by using readonly command. After a variable is marked read-only, its value cannot be changed
- □ For example, following script would give error while trying to change the value of NAME

#!/bin/sh NAME="David Green" readonly NAME NAME="Peter" /bin/sh: NAME: This variable is read only

Example Script

#! /bin/sh

echo -n "Enter first name: " # prompt for first name

read FNAME echo -n Enter last name: read LNAME MESSAGE="Your name is: \$LNAME, \$FNAME" echo \$MESSAGE

-n = no newline # read first name # prompt for second name

no double quotation # necessary

Enter first name: Gulzar Enter last name: Khuwaja Your name is: Khuwaja, Gulzar

Shell Basic Operators

Various operators supported by each shell

- Arithmetic Operators
- Relational Operators
- Boolean Operators
- String Operators

#!/bin/sh

val='expr 2 + 2' # spaces between operators and expressions echo "Total value: \$val"

Total value: 4

Arithmetic Operators

	Operator	Description	Example
	+	Addition - Adds values on either side of the operator	`expr \$a + \$b` will give 30
	-	Subtraction - Subtracts right hand operand from left hand operand	`expr \$a - \$b` will give -10
	*	Multiplication - Multiplies values on either side of the operator	`expr \$a * \$b` will give 200
a=10 b=20	/	Division - Divides left hand operand by right hand operand	`expr \$b / \$a` will give 2
	%	Modulus - Divides left hand operand by right hand operand and returns remainder	`expr \$b % \$a` will give 0
	=	Assignment - Assign right operand in left operand	a=\$b would assign value of b into a
		Equality - Compares two numbers, if both are same then returns true.	[\$a == \$b] would return false.
	!=	Not Equality - Compares two numbers, if both are different then returns true.	[\$a != \$b] would return true.

· All conditional expressions inside square braces with spaces

Arithmetic Operators- Example

#!/bin/sh

a=10 b=20 val=`expr \$a + \$b` echo "a + b : \$val"

val=`expr \$a - \$b` echo "a - b : \$val"

val=`expr \$a * \$b` echo "a * b : \$val"

val=`expr \$b / \$a` echo "b / a : \$val"

val=`expr \$b % \$a` echo "b % a : \$val" if [\$a == \$b]
then
 echo "a is equal to b"
fi
if [\$a != \$b]
then
 echo "a is not equal to b"
fi
Output:
 a + b : 30
 a - b : -10
 a * b : 200
 b / a : 2
 b % a : 0

a is not equal to b

Relational Operators

	Operator	Description	Example
a=10 b=20	-eq	Checks if the value of two operands are equal or not, if yes then condition becomes true.	[\$a -eq \$b] is not true.
	-ne	Checks if the value of two operands are equal or not, if values are not equal then condition becomes true.	[\$a -ne \$b] is true.
	-gt	Checks if the value of left operand is greater than the value of right operand, if yes then condition becomes true.	[\$a -gt \$b] is not true.
	-lt	Checks if the value of left operand is less than the value of right operand, if yes then condition becomes true.	[\$a -lt \$b] is true.
	-ge	Checks if the value of left operand is greater than or equal to the value of right operand, if yes then condition becomes true.	[\$a -ge \$b] is not true.
	-le	Checks if the value of left operand is less than or equal to the value of right operand, if yes then condition becomes true.	[\$a -le \$b] is true.

Relational Operators- Example

#!/bin/sh a=10 b=20	if [\$a -gt \$b] then echo "\$a -gt \$b: a is greater than b"
if [\$a -eq \$b] then echo "\$a -eq \$b : a is equal to b"	echo "\$a -gt \$b: a is not greater than b" fi
else echo "\$a -eq \$b: a is not equal to b" fi	if [\$a -lt \$b] then echo "\$a -lt \$b: a is less than b" else
if [\$a -ne \$b] then echo "\$a -ne \$b: a is not equal to b"	echo "\$a -lt \$b: a is not less than b" fi
else echo "\$a -ne \$b : a is equal to b" fi	

Relational Operators- Example

	Output:
if [\$a -ge \$b] then	10 -eq 20: a is not equal to b
echo sa -ge sb: a is greater or equal to b else	10 -ne 20: a is not equal to b
echo "\$a -ge \$b: a is not greater or equal to fi	10 -gt 20: a is not greater than b
if [\$a -le \$b]	10 -lt 20: a is less than b
then echo "\$a -le \$b: a is less or equal to b"	10 -ge 20: a is not greater or equal to b
echo "\$a -le \$b: a is not less or equal to b" fi	10 -le 20: a is less or equal to b

Boolean Operators

Assume variable a holds 10 and variable b holds 20

Operator	Description	Example
!	This is logical negation. This inverts a true condition into false and vice versa.	[! false] is true.
-0	This is logical OR. If one of the operands is true then condition would be true.	[\$a -lt 20 -o \$b -gt 100] is true.
-a	This is logical AND. If both the operands are true then condition would be true otherwise it would be false.	[\$a -lt 20 -a \$b -gt 100] is false.

Boolean Operators- Example

fi

#!/bin/sh a=10 b=20 if [\$a != \$b] then echo "\$a != \$b : a is not equal to b" else echo "\$a != \$b: a is equal to b"	if [\$a -lt 100 -o \$b -gt 100] then echo "\$a -lt 100 -o \$b -gt 100 : returns true else echo "\$a -lt 100 -o \$b -gt 100 : returns fals fi if [\$a -lt 5 -o \$b -gt 100] then echo "\$a -lt 100 -o \$b -gt 100 : returns true
if [\$a -lt 100 -a \$b -gt 15]	echo "\$a -lt 100 -o \$b -gt 100 : returns fals
then	fi
echo "\$a -lt 100 -a \$b -gt 15 : returns true"	10 != 20 : a is not equal to b
else	10 -lt 100 -a 20 -gt 15 : returns true
echo "\$a -lt 100 -a \$b -gt 15 : returns false"	10 -lt 100 -o 20 -gt 100 : returns true
fi	10 -lt 5 -o 20 -gt 100 : returns false

String Operators

	Operator	Description	Example
	=	Checks if the value of two operands are equal or not, if yes then condition becomes true.	[\$a = \$b] is not true.
a="abc" b="efg"	!=	Checks if the value of two operands are equal or not, if values are not equal then condition becomes true.	[\$a != \$b] is true.
	-Z	Checks if the given string operand size is zero. If it is zero length then it returns true.	[-z \$a] is not true.
	-n	Checks if the given string operand size is non-zero. If it is non-zero length then it returns true.	[-n \$a] is not false.
	str	Check if str is not the empty string. If it is empty then it returns false.	[\$a] is not false.

String Operators- Example

#!/bin/sh	if [-z \$a] then
="abc" ="efg"	echo "-z \$a : string length is zero" else echo "-z \$a : string length is not zero"
if [\$a = \$b]	fi
then echo "\$a = \$b : a is equal to b" else echo "\$a = \$b: a is not equal to b" fi	if [-n \$a] then echo "-n \$a : string length is not zero" else echo "-n \$a : string length is zero" fi
if [\$a != \$b] then echo "\$a != \$b : a is not equal to b" else echo "\$a != \$b: a is equal to b" fi	if [\$a] then echo "\$a : string is not empty" else echo "\$a : string is empty" fi

String Operators- Example

abc = efg: a is not equal to b abc != efg : a is not equal to b -z abc : string length is not zero -n abc : string length is not zero abc : string is not empty

Decision Making

The if...else statement: #!/bin/sh a=10 b=20 if [\$a == \$b] then echo "a is equal to b" elif [\$a -gt \$b] then echo "a is greater than b" elif [\$a -lt \$b] then echo "a is less than b" else echo "None of the condition met" fi a is less than b

Decision Making

The case...esac Statement

#!/bin/sh

FRUIT="kiwi"

case "\$FRUIT" in "apple") echo "Apple pie is quite tasty."

;; "banana") echo "I like banana nut bread."

;; "kiwi") echo "New Zealand is famous for kiwi." ;;

esac

New Zealand is famous for kiwi.

if [\$a -eq 5]	1
then	4
break	5
fi	
a=`expr \$a + 1`	
done	

Introduction

- C's input/output library is the biggest and most important part of the standard library.
- The <stdio.h> header is the primary source of input/output functions, including printf, scanf, putchar, getchar, puts, and gets.

Chapter 22: Input/Output

File Pointers

- Accessing a stream is done through a *file pointer*, which has type FILE *.
- The FILE type is declared in <stdio.h>.
- Additional file pointers can be declared as needed: FILE *fp1, *fp2;

CPROGRAMMING

Copyright © 2008 W. W. Norton & Company. All rights reserved.

CPROGRAMMING

Chapter 22: Input/Output

Standard Streams and Redirection

2

• <stdio.h> provides three standard streams:

File Pointer	Stream
stdin	Standard input
stdout	Standard output
stderr	Standard error

Default Meaning Keyboard Screen Screen

• These streams are ready to use—we don't declare them, and we don't open or close them.

4

Chapter 22: Input/Output

Standard Streams and Redirection

3

• A typical technique for forcing a program to obtain its input from a file instead of from the keyboard:

demo <in.dat

This technique is known as *input redirection*.

• *Output redirection* is similar:

demo >out.dat

All data written to stdout will now go into the out.dat file instead of appearing on the screen.

5

CPROGRAMMING

Copyright © 2008 W. W. Norton & Company. All rights reserved.

Opening a File

- In Windows, be careful when the file name in a call of fopen includes the \ character.
- The call fopen("c:\project\test1.dat", "r") will fail, because \t is treated as a character escape.
- One way to avoid the problem is to use \\ instead of \: fopen("c:\\project\\test1.dat", "r")
- An alternative is to use the / character instead of \: fopen("c:/project/test1.dat", "r")

10

Chapter 22: Input/Output

Opening a File

• fopen returns a file pointer that the program can (and usually will) save in a variable:

fp = fopen("in.dat", "r");
 /* opens in.dat for reading */

• When it can't open a file, fopen returns a null pointer.

Chapter 22: Input/Output	Chapter 22: Input/Output
Modes	Modes
 Factors that determine which mode string to pass to fopen: Which operations are to be performed on the file Whether the file contains text or binary data 	 Mode strings for text files: <u>String</u> <u>Meaning</u> "r" Open for reading "w" Open for writing (file need not exist) "a" Open for appending (file need not exist) "r+" Open for reading and writing, starting at beginning "w+" Open for reading and writing (truncate if file exists) "a+" Open for reading and writing (append if file exists)
Chapter 22: Input/Output	Chapter 22: Input/Output
Modes	Modes
 Mode strings for binary files: String Meaning "rb" Open for reading "wb" Open for writing (file need not exist) "ab" Open for appending (file need not exist) "r+b" or "rb+" Open for reading and writing, starting at beginning "w+b" or "wb+" Open for reading and writing (truncate if file exists) "a+b" or "ab+" Open for reading and writing (append if file exists) 	 Note that there are different mode strings for <i>writing</i> data and <i>appending</i> data. When data is written to a file, it normally overwrites what was previously there. When a file is opened for appending, data written to the file is added at the end.
CPROCRAMMING 14 Copyright © 2008 W. W. Norton & Company. A Modern Approach access contex	CPROGRAMMING 15 Copyright © 2008 W. W. Norton & Company. A Modern Approach second entow

Modes

- Special rules apply when a file is opened for both reading and writing.
 - Can't switch from reading to writing without first calling a file-positioning function unless the reading operation encountered the end of the file.
 - Can't switch from writing to reading without calling a file-positioning function.

16

Chapter 22: Input/Output

Closing a File

- The fclose function allows a program to close a file that it's no longer using.
- The argument to fclose must be a file pointer obtained from a call of fopen.
- fclose returns zero if the file was closed successfully.
- Otherwise, it returns the error code EOF (a macro defined in <stdio.h>).

- The remove and rename functions allow a program to perform basic file management operations.
- Unlike most other functions in this section, remove and rename work with file names instead of file pointers.
- · Both functions return zero if they succeed and a nonzero value if they fail.

CPROGRAMMING

Copyright © 2008 W. W. Norton & Company. All rights reserved. 20

Miscellaneous File Operations

- remove deletes a file: remove("foo"); /* deletes the file named "foo" */
- The effect of removing a file that's currently open is implementation-defined.

CPROGRAMMING

Copyright © 2008 W. W. Norton & Company. All rights reserved.

Chapter 22: Input/Output

CPROGRAMMING

Miscellaneous File Operations

• rename changes the name of a file:

```
rename("foo", "bar");
  /* renames "foo" to "bar" */
```

- rename is handy for renaming a temporary file created using fopen if a program should decide to make it permanent.
 - If a file with the new name already exists, the effect is implementation-defined.
- rename may fail if asked to rename an open file.

22

Chapter 22: Input/Output

Formatted I/O

21

- The next group of library functions use format strings to control reading and writing.
- printf and related functions are able to convert data from numeric form to character form during output.
- scanf and related functions are able to convert data from character form to numeric form during input.

The ...printf Functions

- The fprintf and printf functions write a variable number of data items to an output stream, using a format string to control the appearance of the output.
- The prototypes for both functions end with the . . . symbol (an *ellipsis*), which indicates a variable number of additional arguments:

int fprintf(FILE * restrict stream, const char * restrict format, ...); int printf(const char * restrict format, ...);

• Both functions return the number of characters written; a negative return value indicates that an error occurred.

24

C	PRO	GRAMMING	
_	A Modern	Approach success incluses

Chapter 22: Input/Output

The ...printf Functions

• printf always writes to stdout, whereas fprintf writes to the stream indicated by its first argument:

printf("Total: %d\n", total); /* writes to stdout */ fprintf(fp, "Total: %d\n", total); /* writes to fp */

• A call of printf is equivalent to a call of fprintf with stdout as the first argument.

Chapter 22: Input/Output

...printf Conversion Specifications

- Both printf and fprintf require a format string containing ordinary characters and/or conversion specifications.
 - Ordinary characters are printed as is.
 - Conversion specifications describe how the remaining arguments are to be converted to character form for display.

Chapter 22: Input/Output

Chapter 22: Input/Output	Chapter 22: Input/Output
The scanf Functions	Output Functions
 Errors that cause thescanf functions to return prematurely: <i>Input failure</i> (no more input characters could be read) <i>Matching failure</i> (the input characters didn't match the format string) 	 putchar writes one character to the stdout stream: putchar(ch); /* writes ch to stdout */ fputc and putc write a character to an arbitrary stream: fputc(ch, fp); /* writes ch to fp */ putc(ch, fp); /* writes ch to fp */ putc is usually implemented as a macro (as well as a function), while fputc is implemented only as a function.
CPROGRAMMING A Modern Approach access tendes 32 Copyright © 2008 W. W. Norton & Company. All rights reserved.	CPROGRAMMING A Modern Approach uscess tendes 33 Copyright © 2008 W. W. Norton & Company. All rights reserved.

Output Functions

- putchar itself is usually a macro: #define putchar(c) putc((c), stdout)
- Programmers usually prefer putc, which gives a faster program.
- If a write error occurs, all three functions set the error indicator for the stream and return EOF.
- Otherwise, they return the character that was written.

34

Chapter 22: Input/Output

Input Functions

- getchar reads a character from stdin: ch = getchar();
- fgetc and getc read a character from an arbitrary stream:

ch = fgetc(fp);ch = qetc(fp);

- All three functions treat the character as an unsigned char value (which is then converted to int type before it's returned).
- As a result, they never return a negative value other than EOF. 35

CPROGRAMMING

• If we used "r" and "w" instead, the program wouldn't necessarily be able to copy binary files.

```
int main(int argc, char *argv[])
 FILE *source_fp, *dest_fp;
 int ch;
```

CPROGRAMMING

```
if (argc != 3) {
 fprintf(stderr, "usage: fcopy source dest\n");
 exit(EXIT FAILURE);
```

Chapter 22: Input/Output

CPROGRAMMING

Block I/O

- The fread and fwrite functions allow a program to read and write large blocks of data in a single step.
- fread and fwrite are used primarily with binary streams, although—with care—it's possible to use them with text streams as well.

Chapter 22: Input/Output

Block I/O

- fwrite is designed to copy an array from memory to a stream.
- Arguments in a call of fwrite:
 - Address of array
 - Size of each array element (in bytes)
 - Number of elements to write
 - File pointer

CPROGRAMMING

• A call of fwrite that writes the entire contents of the array a:

Chapter 22: Input/Output Chapter 22: Input/Output Block I/O Block I/O • fwrite returns the number of elements actually • fread will read the elements of an array from a stream. written. A call of fread that reads the contents of a file into • This number will be less than the third argument if the array a: a write error occurs. n = fread(a, sizeof(a[0])),sizeof(a) / sizeof(a[0]), fp); • fread's return value indicates the actual number of elements read. • This number should equal the third argument unless the end of the input file was reached or a read error occurred. C PROGRAMMING 48 49 Chapter 22: Input/Output Chapter 22: Input/Output Block I/O File Positioning

- fwrite is convenient for a program that needs to store data in a file before terminating.
- Later, the program (or another program) can use fread to read the data back into memory.
- The data doesn't need to be in array form.
- A call of fwrite that writes a structure variable s to a file:

50

```
fwrite(&s, sizeof(s), 1, fp);
```

```
CPROGRAMMING
```

Chapter 22: Input/Output

File Positioning

- Although sequential access is fine for many applications, some programs need the ability to jump around within a file.
- If a file contains a series of records, we might want to jump directly to a particular record.
- <stdio.h> provides five functions that allow a program to determine the current file position or to change it.

52

Chapter 22: Input/Output

CPROGRAMMING

File Positioning

- The fseek function changes the file position associated with the first argument (a file pointer).
- The third argument is one of three macros:

• Every stream has an associated *file position*.

beginning of the file.

sequential access to data.

• When a file is opened, the file position is set at the

• When a read or write operation is performed, the

file position advances automatically, providing

51

 In "append" mode, the initial file position may be at the beginning or end, depending on the implementation.

SEEK_SET	Beginning of file
SEEK_CUR	Current file position
SEEK_END	End of file

• The second argument, which has type long int, is a (possibly negative) byte count.

Chapter 22: Input/Output	Chapter 22: Input/Output
File Positioning	File Positioning
 Using fseek to move to the beginning of a file: fseek(fp, 0L, SEEK_SET); Using fseek to move to the end of a file: fseek(fp, 0L, SEEK_END); Using fseek to move back 10 bytes: fseek(fp, -10L, SEEK_CUR); If an error occurs (the requested position doesn't exist, for example), fseek returns a nonzero value. 	 The file-positioning functions are best used with binary streams. C doesn't prohibit programs from using them with text streams, but certain restrictions apply. For text streams, fseek can be used only to move to the beginning or end of a text stream or to return to a place that was visited previously. For binary streams, fseek isn't required to support calls in which the third argument is SEEK_END.

Chapter 22: Input/Output	Chapter 22: Input/Output
File Positioning	File Positioning
 The ftell function returns the current file position as a long integer. The value returned by ftell may be saved and later supplied to a call of fseek: long file_pos; file_pos = ftell(fp); /* saves current position */ fseek(fp, file_pos, SEEK_SET); /* returns to old position */ 	 If fp is a binary stream, the call ftell(fp) returns the current file position as a byte count, where zero represents the beginning of the file. If fp is a text stream, ftell(fp) isn't necessarily a byte count.
