# Asymptotic Analysis of Algorithms 

Chapter 4

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## The Purpose of Asymptotic Analysis

- To estimate how long a program will run.
- To estimate the largest input that can reasonably be given to the program.
- To compare the efficiency of different algorithms.
- To help focus on the parts of code that are executed the largest number of times.
- To choose an algorithm for an application.

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## Running Time

- Most algorithms transform input objects into output objects.
- The running time of an algorithm typically grows with the input size.
- Average case time is often difficult to determine.
- We focus on the worst case running time.
- Easier to analyze
- Reduces risk

## Experimental Studies

- Write a program implementing the algorithm
- Run the program with inputs of varying size and composition
- Use a method like

System.currentTimeMillis() to get an accurate measure of the actual running time

- Plot the results

## Limitations of Experiments

- It is necessary to implement the algorithm, which may be difficult
- Results may not be indicative of the running time on other inputs not included in the experiment.
- In order to compare two algorithms, the same hardware and software environments must be used

## Theoretical Analysis

- Uses a high-level description of the algorithm instead of an implementation
- Characterizes running time as a function of the input size, $n$.
- Takes into account all possible inputs
- Allows us to evaluate the speed of an algorithm independent of the hardware/software environment

## Primitive Operations

- Basic computations performed by an algorithm
- Identifiable in pseudocode
- Largely independent from the programming language
- Assumed to take a constant amount of time
- Examples:
- Evaluating an expression
- Assigning a value to a variable
- Indexing into an array
- Calling a method
- Returning from a method

## Counting Primitive Operations

- By inspecting the pseudocode, we can determine the maximum number of primitive operations executed by an algorithm, as a function of the input size

```
Algorithm arrayMax(A, n)
    currentMax| A[0]
    for i| 1 to n-1 do
        if A[i] > currentMax then
        currentMax| A[i]
return currentMax
```

    \# operations
    
## Estimating Running Time

- Algorithm arrayMax executes $6 \boldsymbol{n}-1$ primitive operations in the worst case. Define:
$a=$ Time taken by the fastest primitive operation
$\boldsymbol{b}=$ Time taken by the slowest primitive operation
- Let $\boldsymbol{T}(\boldsymbol{n})$ be worst-case time of arrayMax. Then

$$
\boldsymbol{a}(6 \boldsymbol{n}-1) \leq \boldsymbol{T}(\boldsymbol{n}) \leq \boldsymbol{b}(6 \boldsymbol{n}-1)
$$

- Hence, the running time $\boldsymbol{T}(\boldsymbol{n})$ is bounded by two linear functions

## Growth Rate of Running Time

- Changing the hardware/ software environment
- Affects $\boldsymbol{T}(\boldsymbol{n})$ by a constant factor, but
- Does not qualitatively alter the growth rate of $\boldsymbol{T}(\boldsymbol{n})$
- The linear growth rate of the running time $\boldsymbol{T}(\boldsymbol{n})$ is an intrinsic property of algorithm arrayMax

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## Constant Factors

- On a logarithmic scale, the growth rate is not affected by
- constant factors or
- lower-order terms
- Examples
- $10^{2} \boldsymbol{n}+10^{5}$ is a linear function
$-10^{5} \boldsymbol{n}^{2}+10^{8} \boldsymbol{n}$ is a
 quadratic function

We will follow the convention that $\log n \equiv \log _{2} n$.

## Seven Important Functions

- Seven functions that often appear in algorithm analysis:
- Constant $\approx 1$
- Logarithmic $\approx \log n$
- Linear $\approx n$
- N -Log- $\mathrm{N} \approx \boldsymbol{n} \log n$
- Quadratic $\approx n^{2}$
- Cubic $\approx n^{3}$
- Exponential $\approx \mathbf{2}^{n}$
- In a log-log chart, the slope of the line corresponds to the
 growth rate of the function.

Classifying Functions

|  | $n$ |  |  |  |
| ---: | :--- | :--- | :--- | :--- |
| $T(n)$ | 10 | 100 | 1,000 | 10,000 |
| $\log n$ | 3 | 6 | 9 | 13 |
| $n^{1 / 2}$ | 3 | 10 | 31 | 100 |
| $n$ | 10 | 100 | 1,000 | 10,000 |
| $n \log n$ | 30 | 600 | 9,000 | 130,000 |
| $n^{2}$ | 100 | 10,000 | $10^{6}$ | $10^{8}$ |
| $n^{3}$ | 1,000 | $10^{6}$ | $10^{9}$ | $10^{12}$ |
| $2^{n}$ | 1,024 | $10^{30}$ | $10^{300}$ | $10^{3000}$ |

Note: The universe is estimated to contain $\sim 10^{80}$ particles.

## Let's practice classifying functions

## Which are more alike?

$$
\mathrm{n}^{1000} \quad \mathrm{n}^{2} \quad 2^{\mathrm{n}}
$$

## Which are more alike?

## Which are more alike?

## $1000 n^{2}$ <br> $3 n^{2}$ <br> $2 n^{3}$

## Which are more alike?

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## Some Math to Review

- Summations
- Logarithms and Exponents
- Existential and universal operators
- Proof techniques
- properties of logarithms:

$$
\begin{aligned}
& \log _{b}(x y)=\log _{b} x+\log _{b} y \\
& \log _{b}(x / y)=\log _{b} x-\log _{b} y \\
& \log _{b} x^{a}=a \log _{b} x \\
& \log _{b} a=\log _{x} a / \log _{x} b
\end{aligned}
$$

- existential and universal operators
$\exists g \forall b \operatorname{Loves}(b, g)$
$\forall g \exists b \operatorname{Loves}(b, g)$
- properties of exponentials:

$$
\begin{aligned}
& a^{(b+c)}=a^{b} a^{c} \\
& a^{b c}=\left(a^{b}\right)^{c} \\
& a^{b} / a^{c}=a^{(b-c)} \\
& b=a^{\log _{a}}{ }^{b} \\
& b^{c}=a^{c^{*}} \log _{a} b
\end{aligned}
$$

## Understand Quantifiers!!!

## $\exists g, \forall b$, loves $(b, g)$

One girl

## $\forall g, \exists b, \operatorname{loves}(b, g)$

Could be a separate girl for each boy.

## Asymptotic Notation ( $O, \Omega, \Theta$ and all of that)

- The notation was first introduced by number theorist Paul Bachmann in 1894, in the second volume of his book Analytische Zahlentheorie ("analytic number theory").
- The notation was popularized in the work of number theorist Edmund Landau; hence it is sometimes called a Landau symbol.
- It was popularized in computer science by Donald Knuth, who (re)introduced the related Omega and Theta notations.
- Knuth also noted that the (then obscure) Omega notation had been introduced by Hardy and Littlewood under a slightly different meaning, and proposed the current definition.

Source: Wikipedia

## Big-Oh Notation

- Given functions $\boldsymbol{f}(\boldsymbol{n})$ and $\boldsymbol{g}(\boldsymbol{n})$, we say that $\boldsymbol{f}(\boldsymbol{n})$ is $\boldsymbol{O}(\boldsymbol{g}(\boldsymbol{n}))$ if there are positive constants $\boldsymbol{c}$ and $\boldsymbol{n}_{\mathbf{0}}$ such that
$\boldsymbol{f}(\boldsymbol{n}) \leq \boldsymbol{c g}(\boldsymbol{n})$ for $\boldsymbol{n}>\boldsymbol{n}_{\mathbf{0}}$
- Example: $2 \boldsymbol{n}+10$ is $\boldsymbol{O}(\boldsymbol{n})$
$-2 \boldsymbol{n}+10 \leq c n$
- $(c-2) n>10$
- $n>10 /(c-2)$
- Pick $\boldsymbol{c}=3$ and $\boldsymbol{n}_{\mathbf{0}}=10$

## Definition of "Big Oh"

$$
\begin{aligned}
& f(n) \in O(g(n)) \\
& \exists c, n_{0}>0: \forall n \geq n_{0}, f(n) \leq c g(n)^{n}
\end{aligned}
$$

## Big-Oh Example

- Example: the function $\boldsymbol{n}^{2}$ is not $\boldsymbol{O}(\boldsymbol{n})$
$-n^{2} \leq c n$
$-\boldsymbol{n}<\boldsymbol{c}$
- The above inequality cannot be satisfied since $c$ must be a constant

## More Big-Oh Examples

- 7n-2
$7 \mathrm{n}-2$ is $\mathrm{O}(\mathrm{n})$ need $\mathrm{c}>0$ and $\mathrm{n}_{0} \geq 1$ such that $7 \mathrm{n}-2 \leq \mathrm{c} \cdot \mathrm{n}$ for $\mathrm{n} \geq \mathrm{n}_{0}$ this is true for $\mathrm{c}=7$ and $\mathrm{n}_{0}=1$
- $3 \mathrm{n}^{3}+20 \mathrm{n}^{2}+5$
$3 n^{3}+20 n^{2}+5$ is $O\left(n^{3}\right)$
need $\mathrm{c}>0$ and $\mathrm{n}_{0} \geq 1$ such that $3 n^{3}+20 \mathrm{n}^{2}+5 \leq \mathrm{c} \cdot \mathrm{n}^{3}$ for $\mathrm{n} \geq n_{0}$ this is true for $\mathrm{c}=5$ and $\mathrm{n}_{0}=20$

■ $3 \log n+5$
$3 \log n+5$ is $O(\log n)$
need $\mathrm{c}>0$ and $\mathrm{n}_{0} \geq 1$ such that $3 \log \mathrm{n}+5 \leq \mathrm{c} \cdot \log \mathrm{n}$ for $\mathrm{n} \geq \mathrm{n}_{0}$
this is true for $\mathrm{c}=4$ and $\mathrm{n}_{0}=32$

## Big-Oh and Growth Rate

- The big-Oh notation gives an upper bound on the growth rate of a function
- The statement " $f(\boldsymbol{n})$ is $\boldsymbol{O}(\boldsymbol{g}(\boldsymbol{n}))$ " means that the growth rate of $f(n)$ is no more than the growth rate of $\boldsymbol{g}(\boldsymbol{n})$
- We can use the big-Oh notation to rank functions according to their growth rate

|  | $\boldsymbol{f}(\boldsymbol{n})$ is $\boldsymbol{O}(\boldsymbol{g}(\boldsymbol{n}))$ | $\boldsymbol{g}(\boldsymbol{n})$ is $\boldsymbol{O}(\boldsymbol{f}(\boldsymbol{n}))$ |
| :--- | :---: | :---: |
| $\boldsymbol{g}(\boldsymbol{n})$ grows more | Yes | No |
| $\boldsymbol{f}(\boldsymbol{n})$ grows more | No | Yes |
| Same growth | Yes | Yes |

## Big-Oh Rules

- If $f(\boldsymbol{n})$ is a polynomial of degree $\boldsymbol{d}$, then $\boldsymbol{f}(\boldsymbol{n})$ is $\boldsymbol{O}\left(\boldsymbol{n}^{d}\right)$, i.e.,

1. Drop lower-order terms
2. Drop constant factors

- We generally specify the tightest bound possible
- Say " $2 \boldsymbol{n}$ is $\boldsymbol{O}(\boldsymbol{n})$ " instead of " $2 \boldsymbol{n}$ is $\boldsymbol{O}\left(\boldsymbol{n}^{2}\right)$ "
- Use the simplest expression of the class
- Say " $3 \boldsymbol{n}+5$ is $\boldsymbol{O}(\boldsymbol{n})$ " instead of " $3 \boldsymbol{n}+5$ is $\boldsymbol{O}(3 \boldsymbol{n})$ "

## Asymptotic Algorithm Analysis

- The asymptotic analysis of an algorithm determines the running time in big-Oh notation
- To perform the asymptotic analysis
- We find the worst-case number of primitive operations executed as a function of the input size
- We express this function with big-Oh notation
- Example:
- We determine that algorithm arrayMax executes at most $6 \boldsymbol{n}-1$ primitive operations
- We say that algorithm arrayMax "runs in $\boldsymbol{O}(\boldsymbol{n})$ time"
- Since constant factors and lower-order terms are eventually dropped anyhow, we can disregard them when counting primitive operations

## Computing Prefix Averages

- We further illustrate asymptotic analysis with two algorithms for prefix averages
- The $\boldsymbol{i}$-th prefix average of an array $\boldsymbol{X}$ is the average of the first $(i+1)$ elements of $X$ :

$$
A[i]=(X[0]+X[1]+\ldots+X[i]) /(i+1)
$$

- Computing the array $\boldsymbol{A}$ of prefix averages of another array $\boldsymbol{X}$ has applications to financial analysis, for example.

## Prefix Averages (v1)

- The following algorithm computes prefix averages by applying the definition

```
Algorithm prefixAverages1(X,n)
    Input array }\boldsymbol{X}\mathrm{ of }\boldsymbol{n}\mathrm{ integers
    Output array }\boldsymbol{A}\mathrm{ of prefix averages of }\boldsymbol{X}\mathrm{ #operations
    A}|\mathrm{ new array of }\boldsymbol{n}\mathrm{ integers n
    for i| 0 to n-1 do
        s|X[0] n
        for j| 1 to ido
        s| s+X[j]
    1+2+\ldots+(n-1)
    A[i]|s/(i+1)
    1+2+\ldots+(n-1)
n
    return A
1
```

## Arithmetic Progression

- The running time of prefixAverages1 is $\boldsymbol{O}(1+2+\ldots+\boldsymbol{n})$
- The sum of the first $n$ integers is $\boldsymbol{n}(\boldsymbol{n}+1) / 2$
- There is a simple visual proof of this fact
- Thus, algorithm prefixAverages1 runs in $\boldsymbol{O}\left(\boldsymbol{n}^{2}\right)$ time

## Prefix Averages (v2)

- The following algorithm computes prefix averages efficiently by keeping a running sum

```
Algorithm prefixAverages \(2(X, n)\)
    Input array \(\boldsymbol{X}\) of \(\boldsymbol{n}\) integers
    Output array \(\boldsymbol{A}\) of prefix averages of \(\boldsymbol{X} \quad\) \#operations
    \(\boldsymbol{A} \mid\) new array of \(\boldsymbol{n}\) integers
    \(n\)
    \(s \mid 0 \quad 1\)
    for \(\boldsymbol{i} \mid 0\) to \(n-1\) do \(n\)
    \(s \mid s+X[i] \quad n\)
    \(A[i] \mid s /(i+1) \quad n\)
    return \(A \quad 1\)
```

- Algorithm prefixAverages 2 runs in $\boldsymbol{O}(\boldsymbol{n})$ time

## Relatives of Big-Oh

$\Delta$ Big-Omega

- $f(n)$ is $\Omega(g(n))$ if there is a constant $c>0$ and an integer constant $n_{0} \geq 1$ such that $f(n) \geq c \bullet g(n)$ for $n \geq n_{0}$
$\Delta$ Big-Theta
- $f(n)$ is $\Theta(g(n))$ if there are constants $c_{1}>0$ and $\mathrm{c}_{2}>0$ and an integer constant $\mathrm{n}_{0} \geq 1$ such that $\mathrm{c}_{1} \cdot \mathrm{~g}(\mathrm{n}) \leq \mathrm{f}(\mathrm{n}) \leq \mathrm{c}_{2} \cdot \mathrm{~g}(\mathrm{n})$ for $\mathrm{n} \geq \mathrm{n}_{0}$

## Intuition for Asymptotic Notation

## Big-Oh

- $f(n)$ is $O(g(n))$ if $f(n)$ is asymptotically less than or equal to $\mathrm{g}(\mathrm{n})$
big-Omega
- $f(n)$ is $\Omega(g(n))$ if $f(n)$ is asymptotically greater than or equal to $\mathrm{g}(\mathrm{n})$
big-Theta
- $f(n)$ is $\Theta(g(n))$ if $f(n)$ is asymptotically equal to $g(n)$

Note that $f(n) \in \Theta(g(n)) \equiv(f(n) \in O(g(n))$ and $f(n) \in \Omega(g(n)))$

## Definition of Theta

$$
\begin{aligned}
& \mathrm{f}(\mathrm{n})=\theta(\mathrm{g}(\mathrm{n})) \\
& \exists c_{1}, c_{2}, n_{0}>0: \forall n \geq n_{0}, c_{1} g(n) \leq f(n) \leq c_{2} g(n) \\
& f(n) \text { is sandwiched between } c_{1} g(n) \text { and } c_{2} g(n)
\end{aligned}
$$

## Overview

- Motivation
- Definition of Running Time
- Classifying Running Time
- Asymptotic Notation \& Proving Bounds
- Algorithm Complexity vs Problem Complexity

## Time Complexity of an Algorithm

The time complexity of an algorithm is the largest time required on any input of size n . (Worst case analysis.)

- $\mathrm{O}\left(\mathrm{n}^{2}\right)$ : For any input size $\mathrm{n} \geq \mathrm{n}_{0}$, the algorithm takes no more than $\mathrm{cn}^{2}$ time on every input.
- $\Omega\left(\mathrm{n}^{2}\right)$ : For any input size $\mathrm{n} \geq \mathrm{n}_{0}$, the algorithm takes at least $\mathrm{cn}^{2}$ time on at least one input.
- $\theta\left(n^{2}\right)$ : Do both.

## What is the height of tallest person in the

 class?Bigger than this?

Need to find only one person who is taller

Smaller than this?

Need to look at
every person

## Time Complexity of a Problem

## The time complexity of a problem is the time complexity of the fastest algorithm that solves the problem.

- $O\left(n^{2}\right)$ : Provide an algorithm that solves the problem in no more than this time.
- Remember: for every input, i.e. worst case analysis!
- $\Omega\left(n^{2}\right)$ : Prove that no algorithm can solve it faster.
- Remember: only need one input that takes at least this long!
- $\theta\left(n^{2}\right)$ : Do both.
